GENERAL INFORMATION

Authors

Manuscripts should be addressed to Arthur H. Wells, M.D., Editor, 915 East First Street, Duluth 5, Minnesota. Telephone RA 7-6636 or JA 5-2319. Original papers prepared for publication solely in Minnesota Medicine will be considered by the Board of Editors providing they fulfill the following editorial standards. Manuscripts should be typed double spaced on white paper with at least 1-inch margins. The original (not a carbon copy) is requested. The title on the first page should be under six words if possible or divided into two parts. The author should give his highest degree, his institutional position or his relationship to a hospital or medical organization which he may be addressing. Pages should be numbered consecutively and the author's last name should appear at the top of each page.

Bibliographical references should appear on a separate sheet entitled References. They should appear and be numbered consecutively in the order in which they first occur in the text (not alphabetically). Citations in the text require reference numbers if the author's or authors' names are not used or if there is more than one reference to the same author or group of authors. All references to author should appear in the list of References and no references should be included which are not in the text. The style and exact punctuation used in the J.A.M.A. references are requested. Journal references should include: *Author's last name, initial., initial.: title of paper. Abbreviated name of journal, volume number: page, year.* Book references should give author, title, edition number, city, publisher and year.

Illustrations (photographs, tables and graphs) should be submitted separately and not combined in the text. There should be a separate sheet entitled "Illustrations" which contains the various types of illustrations listed separately and numbered in the order in which they appear in the text. All photographs must be in black and white, clear cut, contrasting, and on glossy stock. Instructions for combining photographs are acceptable. Any number of illustrations over 4 are charged to the author. Combinations of photographs up to one-half page (6 x 4⅜ inches) count as 1 illustration.

Laboratory Evaluation

Reiter Protein Complement Fixation Test

In the Diagnosis of Syphilis

HENRY BAUER, PH.D.
K. YVONNE PINKE, B.S.
Minneapolis, Minnesota

Dr. Bauer is Director, Division of Medical Laboratories, and, Mrs. Pinke is Chief, Section of Serology, Division of Medical Laboratories, Minnesota Department of Health.

*The Authors are indebted to H. G. Irvine, M.D., Consultant in Charge of Venereal Diseases, Division of Disease Prevention and Control, for his helpful suggestions in the preparation of this paper.

THERE is no single serologic test for syphilis which is sufficiently sensitive to detect every stage of the disease and which at the same time is specific only for syphilis. However, recent developments of serologic tests with antigens obtained from treponemes have increased, within certain limits, the specificity of the tests for syphilis. Protein antigen extracted from Reiter treponeme has received attention since D'Alessandro and Dardanoni[1] selected the Kolmer technique to demonstrate the serologic activity of this antigen. Cannefax and Garson,[2] using this antigen in a one-fifth volume Kolmer test, referred to the procedure as the Reiter protein complement fixation test (RPCF); this test is also referred to in the literature as the Kolmer Reiter protein or KRP test. It will be referred to here as the RPCF test.

During the past year and a half, the Division of Medical Laboratories has been conducting studies with the RPCF test in an attempt to determine the usefulness of this test in the diagnosis of syphilis. Our studies have indicated the RPCF test to be a useful serologic tool to aid in the diagnosis of syphilis. This was determined from laboratory tests and through clinical application of these tests in a cooperative study with Doctors Lynch and Binder.[3] Data are presented demonstrating the laboratory values and limitations of the RPCF test.

Beginning January 1, 1960 the RPCF test will be added to our "battery or special studies," and the Kahn test will be discontinued. The "battery or special studies" are usually performed on two vial specimens selected or requested by the consultant on the venereal disease program, Minnesota Department of Health.

Method and Materials

In our studies we used the Reiter protein antigen, Ryprogen,* in a one-fifth volume Kolmer test (RPCF). The details of this test can be found in the "Manual of Serologic Test for Syphilis."[4]

During our laboratory studies, 285 specimens were subjected to the RPCF test and to the Kline, VDRL, Kolmer, Kahn and Hinton test. The *Treponema pallidum* immobilization test (TPI) was obtained on a few specimens and the results will be presented. Of the 285 serum specimens 195 were from persons who were diagnosed as having syphilis and ninety were from persons in whom no diagnosis of syphilis had been established. The group of ninety specimens were submitted for serologic tests for syphilis either as a part of a routine check-up or part of a clinical work-up of an ill patient. The diagnosis of the clinically ill persons included illnesses or infections such as pneumonia, tuberculosis, infectious mononucleosis,

*Trade name of antigen, Organon, Inc., Orange, New Jersey.

Negative=(−)

diabetes, lupus erythematosus, hepatitis, cancer of the uterus, and influenza. Only one of the ninety specimens was from a patient who gave a history of possible treatment for syphilis. There is no available record on this patient. The information pertaining to the 285 specimens was obtained from data cards accompanying the specimens, case reports or case records.

Test Results

For the purpose of comparing tests, the presentation in Table I is confined to the RPCF, VDRL, and Kolmer tests. Perhaps the outstanding feature in Table I is the demonstration that the RPCF test helps clarify the VDRL and Kolmer test results obtained with the ninety specimens listed under the heading "No Diagnosis of Syphilis." It will be noted that the RPCF test was nonreactive (N) in 52 (58 per cent) of the specimens where there was a combination of (VDRL +, Kolmer +) and (VDRL —, Kolmer +) or (VDRL +, Kolmer —). If the (VDRL —, Kolmer —) specimens are added to this group there are 29 (32 per cent) more non-reacting RPCF tests, making a total of 81 (90 per cent) specimens with "No Diagnosis of Syphilis" yielding a nonreactive RPCF test. It is significant that only 6 (6 per cent) of the specimens tested in this category were reactive with the RPCF test when both the VDRL and Kolmer tests were positive or the VDRL was positive and the Kolmer was negative. The combinations (VDRL +, Kolmer +) and (VDRL +, Kolmer —) or (VDRL —, Kolmer +) with a reactive RPCF test occurred in thirty (60 per cent) of the primary and secondary cases of syphilis, fifteen (100 per cent) of the early latent, fifty-five (63 per cent) of the late latent, five (62 per cent) of the cardiovascular, seventeen (77 per cent) neurosyphilis and only three (23 per cent) of the cases diagnosed as congenital syphilis.

In addition to the 285 specimens reported in Table I, serum specimens from 212 persons who had been vaccinated for smallpox were also examined in our laboratories by the tests described. F. W. Lynch and his associates[5] reported that only

TABLE II. RELATIVE SENSITIVITY OF THE V.D.R.L., KOLMER AND R.P.C.F. TESTS

RPCF-Kolmer	34	68.0	13	86.7	49	56.3	6	75.0	17	77.3	8	61.5	127	65.1	64	71.1	191	67.0
Total specimens	50		15		87		8		22		13		195		90		285	

one serum specimen showed a weakly reactive RPCF test and when the same specimen was re-tested it was non-reactive. On the other hand, fifty-seven serum specimens gave positive tests (reacted) when beef heart antigen was employed. These authors concluded that the fifty-seven specimens were "false reactions" and that the RPCF test has a higher degree of specificity in eliminating "false reactors" due to smallpox vaccine.

The data in Table I is oriented in Table II to show the relative sensitivity of these tests in each of the stages of syphilis and in the "No Diagnosis of Syphilis" group. The RPCF test has the lowest percentage of reactive results in all classifications except under the heading, "Early Latent," where one finds the VDRL and RPCF test equally sensitive.

Table III, which shows the percentage of agreements, demonstrates that the (RPCF, VDRL) and (RPCF, Kolmer) are generally much closer in agreement to one another than either is to the combination (Kolmer, VDRL). There are two distinct exceptions. Under the heading "Congenital" the pair (RPCF, Kolmer) and (Kolmer, VDRL) are in closer agreement than either is to the combination (RPCF, VDRL). This also holds true under the heading "No Diagnosis of Syphilis."

Table IV shows the agreements, partial agreements and disagreements obtained with the same serum specimen subjected to the TPI and RPCF tests. One of the two patients on whom there was a disagreement had a dignosis of late latent syphilis. The first blood specimen received from this patient was reactive in both the RPCF and TPI test; however, a blood specimen received later was non-reactive with the RPCF and reactive with the TPI test. The other of the two patients in the "disagreement column" remains undiagnosed; this person's blood serum was non-reactive in the RPCF and reactive with the TPI test.

TABLE IV. COMPARISON OF AGREEMENTS TPI AND RPCF TESTS WITH SAME SERUM SPECIMEN

Test Combination	Agreements		Partial Agreements		Dis-agreements		Total Patients
	No.	%	No.	%	No.	%	
RPCF-TPI	10	71.4	2	14.3	2	14.3	14

Illustrative Cases

In Table V the results of the serologic tests on a few selected individuals are given. The following brief history obtained from the case record of each individual is presented to demonstrate the relationship of the tests to the final diagnosis.

A. *Non-syphilitic:* She is a seventy-eight-year-old widow under treatment for chronic lymphatic leukemia. It is extremely unusual to see the VDRL positive in such high dilution in a non-syphilitic patient.

B. *Non-syphilitic:* Patient B shows contradictory results which are unlikely in syphilis but are quite characteristic of non-specific reactions. This forty-eight-year-old man is diabetic and was hospitalized at the time the Kolmer and Kahn tests gave a positive reaction.

C. *Primary Syphilis:* Patient C contracted syphilis from her husband (Patient D, a known case). Significant blood changes occurred in the thirty-six-day interval between the first and second specimens with all serologic tests becoming strongly positive except for the RPCF test which remained negative. Penicillin was given between the second and third specimens with the eventual reversion to negative reaction in almost all serologic tests performed.

D. *Primary or Secondary:* Patient D is the husband of case C. The darkfield examination done at the hospital was negative seven days prior to the first blood examination. The first blood was reactive in all tests including the RPCF test. Penicillin was administered between the first and second specimens, with subsequent change in all laboratory tests to a negative reaction.

E. *Secondary:* Patient E was named as a contact for Case F. He is twenty-one years of age, considered to have been infected for at least seven months prior to

TABLE V. ILLUSTRATIVE CASES

collection of the first blood specimen. Treatment was started between the second and third specimens. There was no appreciable change in the RPCF test reactivity although the reagin tests Kahn, Hinton and VDRL tests demonstrated reduced reactivity at the end of a three-month period.

F. *Early Latent:* Patient F named Case E as a contact. There had been frequent exposures during the nine-month period previous to the collection of the first blood specimen. This young woman, aged nineteen was pregnant when first examined. She was treated with Duracillin intermuscularly and achromycin orally prior to the third specimen which was taken at the time of delivery.

G. *Late Latent:* Patient G was diagnosed in 1950. There is no treatment record available. In a period of eleven months there was no change in the serologic test results. The TPI test was reactive.

H. *Late Latent:* Patient H, a man aged forty-three, was treated after the first specimen was collected. After treatment the RPCF test became negative, the TPI test remained reactive and there was little change in the reagin test results.

I. *Cardiovascular Syphilis:* Patient I, a woman aged forty-five, was diagnosed and treated between the first and second specimen. The patient expired two days after collection of the last blood specimen.

J. *Congenital Asymptomatic:* Patient J is a forty-eight-year-old woman with three grown children in good health. The TPI test is weakly reactive.

Discussion

The basic difference between the RPCF test and the Kolmer test is principally the antigen and quantities of reagents used. Also, because the antigen in the RPCF is derived from a treponeme it is believed to be more specific than the Kline, VDRL, Kolmer, Kahn, and Hinton tests wherein one uses as an antigen either cardiolipin (beef heart) sensitized with lecithin and cholesterol or cardiolipin (beef heart) sensitized only with cholesterol.

The sensitivity of the various tests are dependent on the presence of the particular antibody which will react with the particular antigen used in the test and the differences of technique inherent in each test. D'Alessandro and his coworkers,[6] in their studies of the Reiter protein antigen state, "The antibody against treponema specific antigen of proteic nature are definitely demonstrable in every case of secondary and some cases of primary syphilis, even if reagin is lacking. Their presence is irregular in older infections and

treated cases. In some cases of late congenital syphilis treponemal antibodies are not demonstrable while reagin is still present in significant amounts." The results shown in Table II and particularly those under the heading "Congenital" conform to their statement. When one compares the per cent of positive reactions of each test for all syphilitic groups, it is noted that the VDRL is most sensitive and the RPCF is least sensitive of the three tests.

In a study conducted by Cannefax and Garson[2] they concluded that the RPCF test had a relative specificity of 98.86 per cent in comparison to the *Treponema pallidum* immobilization test (TPI). Accordingly, there should be very few occasions when the TPI test would be needed as an additional aid in the diagnosis of syphilis. The RPCF test, in addition to the Kolmer and VDRL tests, correlated with the clinical evidence and the patient's history will, in the great majority of instances, delineate the diagnosis of syphilis. Rarely should one find a biological false positive (BFP) reacting serum if the VDRL and Kolmer tests are positive and the RPCF test is reactive. However, should it be necessary to request a TPI test, certain criteria must be met before the specimen will be accepted by the U. S. Public Health Service Venereal Disease Research Laboratories. This laboratory performs the TPI test for the Minnesota Department of Health and other state health department laboratories. The patient must be a diagnostic problem with no history or clinical evidence of syphilis. All available serologic testing of serum (and, if possible, spinal fluid), should be completed and evaluated before requesting the TPI test.

A negative VDRL and Kolmer test combined with a non-reactive RPCF test is generally conclusive that the patient does not have syphilis, providing there is no clinical evidence or history of syphilis and that blood was not collected so early in the infection that there was insufficient time for antibodies to develop. In cases where blood specimens are collected too early in the infection, additional blood specimens should be submitted once or twice a month for about three months on all persons who had a suspected syphilitic chancre and whose serology tests were negative. Also, whenever there is a question regarding the diagnosis of syphilis, repeated laboratory studies should be made.

The RPCF will be performed only on "two-vial" specimens which have been requested by the Consultant on Venereal Diseases, Minnesota Department of Health, or where there is a question regarding biological false positive reactions. The RPCF test will be performed on Monday and Wednesday of each week. Accordingly, the reports of specimens subjected to RPCF test will be delayed for at least three days.

Summary

1. Effective January 1, 1960, the Reiter protein complement fixation test (RPCF) will be done on all "two vial" specimens, selected specimens or specimens requested by the Consultant on Venereal Diseases, Minnesota Department of Health, or where there is a question regarding biological false positive test for syphilis.

2. The Kahn test will be discontinued in the "battery testing" and will be replaced by the RPCF test.

3. The RPCF test will be performed on selected specimens twice weekly. Accordingly, there will be a delay of about three days in reporting the results on such specimens.

4. The RPCF test in combination with the Kolmer and VDRL correlated with clinical evidence and history should serve effectively in delineating the diagnosis of syphilis.

5. Requests for TPI test will be honored only after there have been repeated VDRL, Kolmer, and RPCF tests and there is clinical evidence to doubt that the results indicate syphilis. Arrangements for submission of specimens for TPI testing should be made before collecting blood.

Reiter Protein Complement Fixation Test

In the Diagnosis of Syphilis

A Clinical Evaluation

Dr. Lynch and Dr. Binder, respectively, are Clinical Professor and Director of the Division of Dermatology, and Medical Fellow in the Division of Dermatology, Medical School of the University of Minnesota.

IT WAS the purpose of this study to review the clinical effectiveness of the Reiter Protein Complement Fixation Test (RPCF) as conducted in the serologic laboratory of the Minnesota Department of Health and it is the purpose of this paper to present to Minnesota physicians the results of the study and thereby to make them familiar with this additional procedure which is soon to be offered them in selected cases of serologic specimens submitted for aid in the diagnosis or exclusion of syphilis.

Among the most dependable of all clinical laboratory procedures have been the standard Serologic Tests for Syphilis (STS). It is generally accepted that they have a specificity rate of 99 per cent, when carried out in approved laboratories. Therefore, it may come as a surprise to many physicians that improvement is sought by serologists and syphilologists. To them the problem of reactivity to STS is particularly of grave concern when not given support by positive clinical history or physical findings, because of the possibility that the reaction represents a biologic false positive reaction (BFP) not due to syphilis. Known, but not generally appreciated by physicians, is the important fact that the standard STS are not fundamentally "specific" in their structure, utilizing as antigens proteins which are not derived from the causative organisms of syphilis or related organisms and whose sources are animal tissue unaffected by treponemal disease currently or in the past.

A valuable improvement in serologic testing for syphilis was achieved by Nelson in 1949 with the use of a specific antigen in the *Treponema pallida* Immobilization (TPI) test. The TPI test has since become highly regarded as an aid in distinguishing biologic false positives from positive reactions due to syphilis. Subsequently other tests which use antigens derived from *T. pallidum* have shared with the TPI test the disadvantages of high cost and limited availability until recently d'Allesandro and associates developed a less expensive test, the Reiter Protein Complement Fixation (RPCF) test, whose antigen is derived from the non-pathogenic Reiter strain of treponeme. This test has been evaluated in several extensive serologic surveys and has recently been used experimentally at the Minnesota Department of Health Laboratories. The results of this test were studied by the authors as applied to specimens submitted by Minnesota physicians in recent months.

Procedure

Serologic reports and clinical data for the 146 persons in Group I were made available to us largely from records collected by the Minnesota Department of Health since 1918.[1] These 146 persons consisted of: (a) eighty-six patients reported as having syphilis, the majority having been treated, (b) sixteen persons having reactive or weakly reactive standard serologic tests for syphilis but regarded as biologic false positive (BFP) reactors, (c) forty-four patients with reactive or weakly reactive STS but where the clinical evidence was insufficient to justify either the diagnosis or the exclusion of syphilis.

Additional clinical information, records of treatment, multiple STS and RPCF tests and results on spinal fluid examinations were obtained for as many of the patients as possible. The data were used for a more detailed classification of these patients without knowledge of the result of the RPCF (Tables IA and IB). For twenty Group I patients, TPI test results were available from the United States Public Health Service, Communicable Disease Center, Chamblee, Georgia.

Group II consisted of 212 university students undergoing physical examination on admission to school; it is thought that none previously or currently had syphilis. Blood specimens were collected from these students nineteen to fifty-two days following smallpox vaccination on the assumption, based on previous experience[2] and the report of others, that the vaccinia would produce biological false positive reactors useful for this study. Ninety-seven of the students had shown a primary reaction to vaccinia and 115 had shown an accelerated reaction; students showing an immune reaction were not tested. These specimens provided BFP reactions to STS from fifty-seven persons, thereby offering opportunity for a severe test of the RPCF technic on comparative studies.

The STS performed on the specimens from both groups of patients included three technics using cardiolipin cholesterol antigens (Standard Kahn, Hinton and Kolmer-Wassermann) and two

using cardiolipin - lecithin - cholesterol antigens (Kline and VDRL). These five tests and the RPCF test were performed as described in the accompanying paper which immediately precedes this report.

Results

Results of the tests (Table II) were reported as they will be given to Minnesota clinicians by the Minnesota Department of Health.[3]

1. *Reactive:* This is equivalent to 1+, 2+, 3+ or 4+, "positive" reactions on previously used STS.
2. *Weakly reactive:* This is the equivalent of previous reports of "doubtful."
3. *Non-reactive:* Equivalent to "negative."
4. *Anticomplementary:* As used with older serologic tests and as described in the immediately preceding paper in this journal. (Five sera reacted in this manner.)

RPCF Reactors.—On specimens from seventy-three of the 146 persons in Group I the RPCF test report was "reactive":

1. In sixty-three instances the STS and available clinical information made the diagnosis of syphilis practically certain. Four of these patients also had reactive TPI tests.

2. In five additional instances the STS were positive but there was no confirmatory clinical information. However, in three of these patients the impression of syphilis given by the RPCF test was confirmed by reactivity to the more highly specific TPCF and TPI tests.

3. The remaining five patients had doubtful or conflicting STS reports and no known clinical evidence of syphilis. In two of the five patients the impression of syphilis given by the RPCF test was confirmed by reactivity to the TPCF and TPI tests. In one there were no clinical data available and therefore there can be no judgment on the accuracy of the RPCF versus the STS. Two of the patients were elderly and presented serious systemic disease which may have produced BFP reactions to both types of test.

On the basis of the above results one judges that an RPCF report of "reactive" most likely signifies the presence of syphilis. The exact percentage of accuracy could not be measured in a survey such as this.

Weakly Reactive RPCF.—In this series most of the weakly positive reactions to the RPCF test became clearly reactive or non-reactive on retesting the same specimen of serum or another specimen submitted later.

Weakly positive reaction to the RPCF tests occurred in nine instances with no opportunity to examine another specimen. In two where the TPI was also used the results were confirmatory in one and uncertain in the other. In the remainder the STS report was doubtful in four and positive in three. In all but three of the patients a diagnosis of syphilis had been made and treatment given years previous to performance of the RPCF test. The weakly reactive RPCF report probably indicates the presence of syphilis unless the clinical data strongly suggest the possibility of a BFP result.

RPCF Non-Reactors.—On fifty-five patients the RPCF test report was "non-reactive."

1. In thirty-two instances the STS reports were doubtful and there was no other evidence of syphilis. (It is to be recalled at this point that under the conditions of this study Group I did *not* include patients with "negative" reports on STS.) In five of these the TPI test also was non-reactive; in one more it was reported only weakly reactive; in these six instances the RPCF test was probably correct. In one of the thirty-two, the results of the TPI and RPCF tests were not conclusive. Three of the thirty-two patients were pregnant; one had disseminated lupus erythematosus and one had diabetes mellitus; these five may have been BFP reactors to the STS, with the RPCF test correct.

2. In thirteen instances there were doubtful

STS reactions but the patients had had previous treatment for syphilis. In five of these, treatment had begun in the primary stage; four had been treated for congenital syphilis; three were elderly persons with syphilis of long duration and having received much treatment; and one was a young person having had very much treatment five years previously.

3. In four instances the STS reports were "positive" but unsupported by clinical evidence of syphilis. One had leukemia, one had arteriosclerotic heart disease and the third had severe hypertension, possible causes of BFP reactivity. One had been treated for syphilis though not reported as definitely diagnosed, having chronic lumbar osteomyelitis and having lived in the Sudan (BFP reactor?).

4. In six additional instances where the STS reports were "positive" three had much previous treatment for syphilis of long duration and three were elderly persons having had much treatment.

On the basis of the above results it seems that when the RPCF test is reported "non-reactive" this may indicate several possibilities:

1. If the STS report is "negative" then the presence of syphilis is unlikely. (Patients like this were not included in this study.)

2. If the STS is ± and (a) there is no other evidence of syphilis a BFP reaction to the STS is probable and likely; (b) if there has been previous treatment for syphilis the non-reactive RPCF report may indicate possible cure after effective treatment of early syphilis, congenital syphilis, or syphilis of long duration.

3. If the STS is + and there is no other evidence of syphilis a false positive STS reaction is probable. If treatment has been given previously, the non-reactivity of the RPCF may represent the result of treatment of syphilis of long duration.

Primary Syphilis.—Six patients were in the primary stage of syphilis. Analysis of their STS and RPCF results is given in Table II. The data show that the RPCF was reactive only when the STS was positive or doubtful, not when negative. This delay in development of RPCF reactivity has been commented upon by other authors. After treatment the RPCF may convert from reactive to non-reactive.

Among the patients who had early syphilis two to fifty-six years ago and who then had reasonably prompt therapy most remain RPCF reactive now (Table III.) In contrast most of them now have only doubtful STS reactions. Of three non-reactors to the RPCF, one still has a positive STS reaction.

TABLE III. CASES FOLLOWED SINCE PRIMARY STAGE OF SYPHILIS

Case Number	Type of Syphilis*	Duration of Disease (Years)	STS Results	RPCF Results
3	C-V	32	±	R
16	L.L.	12	±	NR
28	L.L.†	56	+	NR
31	C.N.S.	15	+	R

113	L.L.	39	±	R
129	L.L.	31	±	R
149	C.N.S.	26	+	R
160	L.L.	7	±	NR

*Cardiovascular, late latent, neurological, early latent respectively.
†The diagnosis may be incorrect, and no record of treatment is available. The patient had acute encephalitis in 1935.

RPCF Anticomplementary Group.—There were five patients in whom only one serologic specimen was submitted and in whom the RPCF was reported anticomplementary (AC). Two of these patients had been treated for syphilis some years ago. The other three patients had no clinical history of syphilis, and two of them had non-reactive TPI tests. All five patients had doubtful STS. Because the anticomplementary report is of no help to the physician, further serologic studies are indicated.

RPCF Inconsistent Group.—The RPCF test was performed once on all patients included in this study. However, for twenty-two patients from whom further blood specimens were obtained, the test was performed on two, three or even four specimens. For eighteen of these patients the additional tests gave results that were consistent with the first one. In four patients RPCF tests performed on specimens submitted later in the study gave different results.

In one instance of primary syphilis, the RPCF was first reactive when the STS had become reactive. Four months following treatment the STS became doubtful and the RPCF non-reactive on two occasions.

In a patient with untreated secondary syphilis the RPCF changed from weakly reactive to non-reactive. Shortly after treatment the RPCF was

reactive. One wonders if the non-reactive reaction was due to technical error.

In another instance the clinical history was negative and the STS doubtful. RPCF was reactive

TABLE IV. CONGENITAL SYPHILIS

Case Number	Age—(Years)	STS Results	RPCF Results
8	40	±	NR
47	41	±	NR
65	20	±	NR
143	52	±	NR
34	47	+	R
72	20	+	R
102	27	+	R

as was TPI. Treatment was then given, and the RPCF was reported non-reactive ten weeks following therapy. Eight months later, TPI was still reactive and RPCF still non-reactive.

In an elderly patient having neurosyphilis treated adequately many years previously, the RPCF of February was reported weakly reactive and the test of October was reported reactive.

The RPCF may convert to non-reactive following prompt treatment of early syphilis. When the RPCF becomes reactive after being non-reactive or weakly reactive the clinical data and STS should be reviewed. Further serologic testing may be necessary.

Congenital Syphilis.—Seven adult patients having had congenital syphilis were included in this study; all had previous "adequate" antisyphilitic therapy. In four of these patients the STS were doubtful or conflicting and the RPCF non-reactive. In three patients the STS were positive and the RPCF were reactive. These serologic data indicate patients who are serologically "fast" or resistant, and the RPCF results are confirmatory in each instance (Table IV). It is possible that the non-reactive RPCF results were a better index of the response to treatment and a possible cure than were the ± STS.

BFP From Vaccinia.—Specimens from 212 university students collected following primary or accelerated reactions to vaccinia (Group II) served as a non-syphilitic control group and also presented a severe challenge to the RPCF test because vaccinia frequently stimulates BFP reactions to *non*-treponemal antigens. BFP reactions to the several STS for which non-treponemal antigen were used, varied from eight (4 per cent) reactions with the VDRL test to as many as forty-eight (23 per cent) reactions with the Hinton test. A total of fifty-seven persons (27 per cent) reacted falsely to one or more STS; none of these persons showed reactivity to the RPCF. There was weak reactivity to the RPCF test on one person with negative STS. A subsequent RPCF test on the same serum specimen was nonreactive. This lack of repeatability suggests two possibilities: that the reaction was due to technical error (likely) or that the reaction was due to a potentiality for vaccinia to produce BFP reactions to the RPCF test without simultaneous BFP to the STS (unlikely). Additional results and discussion on this group of tests were presented before the Society for Investigative Dermatology and will be published in the *Journal for Investigative Dermatology.*[4]

On the basis of this experience (at least with vaccinia) the RPCF test is less likely to react falsely than is the STS.

Comment

In most of the cases of reactivity to the RPCF test there was some confirmatory evidence of syphilis. In no case was there strong reason to doubt the presence of syphilis though one cannot be certain that there were no examples of false reactivity to the RPCF tests.

In cases where doubtful or conflicting reactivity to standard serologic tests is accompanied by non-reactivity to the RPCF there existed several possibilities: (1) The RPCF is falsely negative. (2) The STS is falsely positive. (3) In some instances decision may be impossible without long observation of the patient. When in the absence of previous treatment the STS is reported doubtful and the RPCF non-reactive the latter is most likely correct and should be depended upon unless the clinical history (personal or familial) gives evidence to the contrary.

After administration of antisyphilitic treatment: if the STS is more strongly positive than the RPCF, the latter may be a better indicator of satisfactory response to treatment; or if the RPCF is non-reactive a positive or doubtful STS report may represent false positive reactivity which lead to an incorrect diagnosis of syphilis at the time the treatment was instituted.

The Use of the Ileum in Urinary Diversion

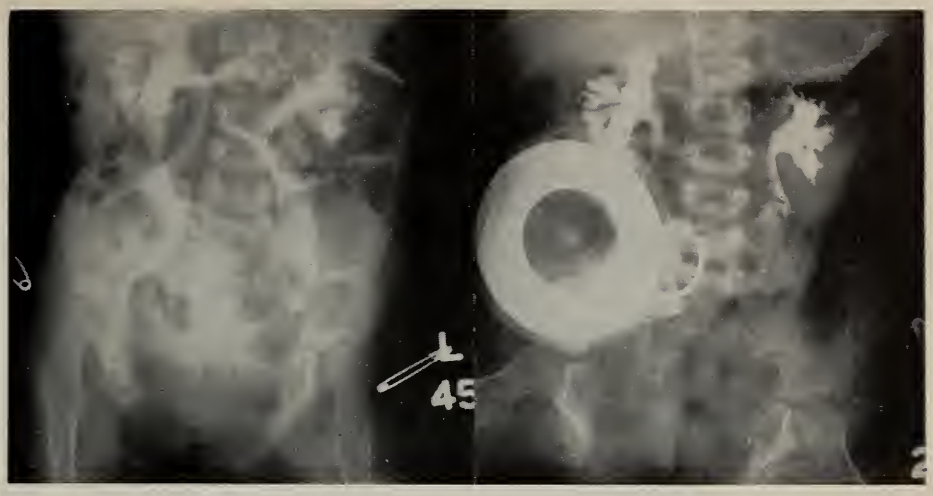

Fig. a. Fig. b.

Fig. 2. (a) Excretory urogram following ureterosigmoidostomy prior to ureteroileostomy. (b) Excretory urogram six weeks following ileal diversion. There has been a considerable reduction in hydronephrosis and hydroureter.

● *The use of terminal ileum as a conduit to divert urine from the ureters to the anterior abdominal wall has been applied in seventeen patients by these authors. There was no surgical mortality in this series. This operation could be useful and satisfactory in the majority of instances.*

LLOYD D. MAC LEAN, M.D.
LYLE A. TONGEN, M.D.
Saint Paul, Minnesota

Presented at the Saint Paul Surgical Society, March 18, 1959.

THE FIRST ATTEMPT at diversion of the urine to the intestinal tract in the human being was made by Sir John Simon in the year 1851 on a patient with extrophy of the bladder.[1] Since that time, a number of operations have been devised. The methods for diversion of the urine to the intestine fall into three categories: (1) implantation of the ureter into the intact intestinal tract, (2) implantation into a completely excluded portion of the intestine, and (3) implantation into a partially excluded portion of the intestine. Until recently, ureterosigmoidostomy has been the most popular method. Dissatisfaction with this procedure due to the high incidence of hydronephrosis, pyelonephritis and electrolyte imbalance has led many to adopt ureteroileostomy as described by Bricker.[2] It is the purpose of this communication to outline our results with the latter procedure in seventeen patients.

Indications

The indications for surgery and the clinical data of interest in these patients is summarized in Table I. The procedures performed were: (1) cystectomy, panhysterectomy, iliac node dissection and diversion of urine to a segment of ileum in 5 patients, (2) cystectomy, prostatectomy, iliac node dissection and diversion of urine to a segment of ileum in three patients, (3) diversion of the urine to an isolated segment of ileum only, for palliation in two patients, for extrophy of the bladder in two patients, and for neurogenic dysfunction of the urinary bladder in five patients. The patients with neurogenic dysfunction had a primary diagnosis of either spina bifida or traumatic section of the spinal cord. In each instance, repeated attacks of pyelonephritis prompted ureteroileostomy.

TABLE I.

Patient	Age	Sex	Diagnosis	Date of Operation	Procedure	Comment
T.L.	58	F	Metastatic carcinoma of bladder from stomach.	9-16-55	Palliative ileal diversion.	Relief of bladder pain. Died 10-14-55.
C.U.	68	M	Carcinoma of bladder.	11-22-55	Total cystectomy node dissection. Ileal diversion.	Died of metastatic carcinoma 4-15-58.
I.L.	63	F	Carcinoma of bladder.	6- 8-56	Total cystectomy, panhysterectomy, excision vagina, vulva, urethra, iliac node dissection. Ileal diversion.	Right inguinal node dissection on 8-1-56—metastatic tumor. No evidence of recurrence—3-1-59.
L.T.	74	F	Carcinoma of bladder.	6-19-56	Palliative ileal diversion.	Died 9-15-56.
P.L.	11	F	Spina bifida urinary incontinence, pyelonephritis.	7-24-56	Ileal diversion.	Stricture of ileostomy with recurrence of pyelonephritis. Repaired 1-8-58. Well since.
M.R.	20	F	Spina bifida urinary incontinence, pyelonephritis.	1- 8-57	Ileal diversion. Removal of bladder stone.	Complete relief of bladder pain and attacks of pyelonephritis.
A.M.	40	M	Fracture spine, paraplegia, urinary incontinence, phelonephritis.	2-26-57	Ileal diversion.	Recurrent pyelonephritis since operation. Symtomatically improved.
C.K.	58	M	Carcinoma of bladder.	4-29-57	Total cystectomy, prostatectomy, iliac node dissection. Ileal diversion.	Alive and well.
S.G.	6	F	Extrophy of bladder, previous ureterosigmoidostomy.	9- 3-57	Ileal diversion.	Considerable improvement and weight gain.
L.E.	54	M	Carcinoma of bladder.	1- 9-58	Total cystectomy, prostatectomy, iliac node dissection, ileal diversion.	Postoperative ileus. Re-operated upon on 1-16-58. Has done well since.
B.M.	4	F	Spina bifida urinary incontinence, pyelonephritis.	4- 1-58	Ileal diversion.	Stricture of ileostomy.
E.A.	54	M	Carcinoma of bladder.	5- 5-58	Total cystectomy, iliac node dissection, ileal diversion.	Developed fecal fistula, renal stones, recurrent pyelonephritis, hyperchloremic acidosis without evidence of urinary obstruction.
K.L.	27	M	Extrophy of bladder, epispadias, pyelonephritis.	5-20-58	Repair epispadias. Excision of bladder. Ileal diversion.	Relief of symptoms.
A.M.	58	F	Carcinoma of bladder.	8-13-58	Total cystectomy, oophorectomy, iliac node dissection, excision vagina, urethra. Ileal diversion.	Alive and well.
A.N.	59	F	Carcinoma of bladder.	11-17-58	Total cystectomy, panhysterectomy, iliac node dissection. Ileal diversion.	Small retropubic abscess drained in postoperative period.
L.S.	29	M	Cervical fracture, quadraplegia, urinary incontinence, pyelonephritis.	1- 6-59	Ileal diversion.	Relief of pain, fever.
C.F.	56	M	Carcinoma of bladder.	2- 4-59	Total cystectomy, prostatectomy, iliac node dissection. Ileal diversion.	

Morbidity and Mortality

There have been three deaths, none related to creation of an ileal conduit for urine. The first patient in this series was operated upon in September, 1955, for metastatic carcinoma of the bladder from the stomach associated with hematuria and severe dysuria. Ileal diversion without resection was carried out with relief of symptoms and marked reduction in hydronephrosis. However, the patient died a month following surgery.

The second death occurred three months following palliative ileal diversion for primary carcinoma of the bladder. The third death resulted from metastatic carcinoma two and one-half years following total cystectomy, prostatectomy and iliac node dissection performed for primary carcinoma of the bladder.

Significant morbidity developed in six of the seventeen patients (Table II). Severe ileus which prompted re-exploration of the abdomen was encountered once. Stricture of the ileal stoma occurred twice in children and was the direct result of an ileostomy bag which was not cemented to the skin but held on loosely with straps. The stoma was revised in each instance without further difficulty. The case histories of the final two patients in Table II are summarized as follows:

TABLE II. MORBIDITY ENCOUNTERED FOLLOWING URETERO-ILEOSTOMY

Severe ileus	1
Stricture of ileal stoma	2
Retropubic abscess	1
Thrombophlebitis, fecal fistula, persistent urinary tract infection, renal stone formation, uremia and hyperchloremia	1
Persistent uremia with hyperchloremia	1

Case Histories

Case 1.—S. G., a six-year-old girl, was hospitalized July 30, 1957, with a pathological fracture of the left femur (Fig. 1a). There was no history of injury. Past history revealed that the patient was born with extrophy of the bladder, which was treated at age fourteen months by bilateral uretero-sigmoidostomy and excision of the bladder. Following this procedure the child was listless with a poor appetite and exhibited retarded physical development. She first began walking at the age of six at which time her weight was 26 pounds. Study revealed severe hyperchloremic acidosis (Table III), with generalized osteoporosis and roentgen changes of rickets (Fig. 1a).

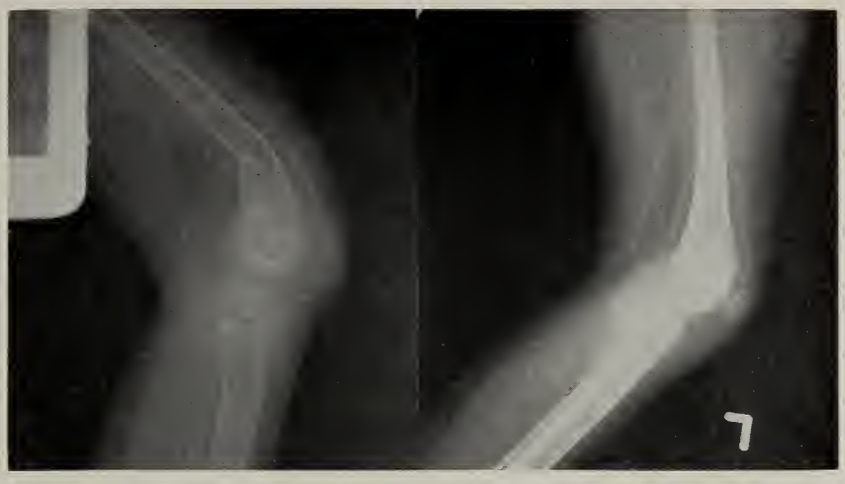

Fig. 1. (a) Roentgenogram of left femur, tibia and fibula of patient, S. G., aged six. Note the extensive demineralization and rachitic changes. The pathological fracture of the femur occurred when walking was first started at age six. The patient had undergone ureterosigmoidostomy at age fourteen months. (b) Three months after diversion of the urine to a segment of ileum. Note the marked improvement of bony structure.

Ileal diversion of the urine was performed on September 3, 1957, after intensive therapy with rectal irrigations and drainage and parenteral fluids had returned the blood chemistries towards normal. The patient improved considerably following surgery despite uremia and periodic acidosis. The child gained to forty-seven pounds by January, 1959, with marked improvement of bony structure (Fig. 1b). There has been a definite reduction in the hydronephrosis noted preoperatively (Figs. 2a and 2b).

Comment.—This patient developed the three major complications of uretero-sigmoidostomy, hydronephrosis, pyelonephritis with impaired renal function and severe hyperchloremic acidosis. While there has not been a complete recovery in renal function following uretero-ileostomy, marked improvement of hydronephrosis and electrolyte balance is evident.

Case 2.—E. A., a fifty-four-year-old man, developed frequency and dysuria in September, 1957. Cystoscopy January 9, 1958, by Dr. E. J. Richardson, revealed squamous cell carcinoma involving the vesicle neck and right wall of the bladder. Transurethral resection was carried out at that time but extensive recurrence was apparent on April 25, 1958, which involved the trigone and right ureteral orifice.

Total cystectomy with iliac node dissection and urinary diversion to an ileal segment was carried out on May 5, 1958. The pelvic floor was reperitonealized. The patient did well initially after surgery, but he was readmitted on June 6, 1958, for drainage of a small abscess in the retropubic space. Thrombophlebitis developed and fecal drainage from the region of the retropubic space was noted. The latter was due to rupture of a diverticulum of the colon for which a defunctionalizing colostomy was performed. A urinary tract infection with hyperchloremic acidosis developed at this time. In December, 1958, further study was prompted by the patient's complaint of back pain and the discovery of persitent urinary tract infection. Pyelograms revealed numerous renal stones. There was no evidence of obstruction in the genitourinary tract. Prior to this the patient drank up to 1 gallon of milk each day and took little other nourishment. The patient has improved recently on a regimen of Furadantin and Basaljel. The blood urea nitrogen has returned to normal on this regimen for the first time since operation.

Comment.—This patient developed a persistent urinary tract infection (Proteus and Pseudomonas) and renal stone formation without demonstrable urinary tract obstruction following uretero-ileostomy. Hyperchloremic acidosis has been an additional problem in this patient.

Blood Chemistry

Preoperative and postoperative values for blood urea nitrogen, carbon dioxide combining power, serum chloride, sodium and potassium on all seventeen patients are summarized in Table IV. While serum chloride elevation above normal (105 mEq/L) is seen frequently, clinically significant hyperchloremic acidosis is unusual. Hyperchloremic acidosis is most likely to occur in patients with impaired renal function (Case 1).

Transient periods of hyperchloremic acidosis were noted in the patients who developed strictures of the ileum at the skin and in patients in whom catheters were used for drainage of the ileal segment. In the latter instance, the catheters were partially obstructed with mucus from the intestine. We have no evidence to support the concept[3] that hypokalemia is related to hyperchloremic acidosis encountered in these patients.

In Table IV, the range of chemistry values following operation is given with the most recent value preceding.

Pyelonephritis

Pyelonephritis has occurred following uretero-ileostomy in four of the seventeen patients. This was related to stricture of the ileal stoma in two patients and has not recurred since it was corrected. Many of the patients in this series had infected urine prior to uretero-ileostomy which has persisted since surgery. However, with the above exceptions these patients have been free of the clinical manifestations of pyelonephritis.

Pyelography

Pre- and postoperative pyelograms have been performed on sixteen of the seventeen patients. Those patients with obstructive uropathy prior to uretero-ileostomy are usually returned to normal or demonstrate only minimal hydronephrosis on intravenous pyelography.

In the absence of strictures at the ureteral anastomoses or at the ileal stoma the kidneys and ureters are likely to remain the same or to improve if mechanical obstruction preceded operation.

Discussion

The multiplicity of operative procedures that have been devised for diversion of the urine from the bladder is an indication that no one procedure is completely satisfactory. Possible advantages of the Bricker procedure[4] over many previously described are: (1) the ileal segment is isolated from the fecal stream which serves to decrease the incidence of pyelonephritis, (2) no sphincter exists to inhibit the flow of urine, (3) the ileal segment is a conduit rather than reservoir thereby decreasing absorption and back-pressure, (4) mucosa to mucosa and mucosa to skin anastomoses are made to decrease the incidence of stricture formation, and (5) a short ileal segment is used to decrease absorption.

While uretero-ileostomy has probably decreased the incidence of pyelonephritis, hydronephrosis and electrolyte imbalance, these complications have not been eliminated. Of equal concern is the fact that diversion of the urine to an isolated ileal segment has increased the incidence of other complications principally intestinal obstruction, and urinary fistula.[5] The latter complications have not occurred in the present small series.

Despite apparent inadequacies and without long term evaluation of the effects of implantation of the ureters into an isolated segment of ileum, this operation appears to be the best available method for urinary diversion at the present time. An improvement for the future could include decreasing the surface area of the ileal segment by removing the villi or lining the ileal segment with a less efficient absorptive surface. A recent report of experimental work by Martin, Duxbury and Leadbetter[6] would indicate that the latter is feasible. These workers were able to graft patches of urinary bladder epithelium to isolated segments of ileum being used as substitutes for the ureters in dogs.

Summary and Conclusions

1. The results have been documented in seventeen patients who underwent diversion of the urine to a segment of ileum as advocated by Bricker.[4]

2. The operation was performed for malignant disease in ten patients, for extrophy of the bladder in two patients and for neurogenic urinary bladder in five patients.

3. There have been no deaths directly attributable to the creation of an ileal conduit for urine. There have been three deaths due to carcinoma at one month, two and one-half months, and two and one-half years following the operation. The operation was least gratifying in the palliative treatment of carcinoma involving the bladder.

4. There has been a low morbidity related to the operation and in most instances the complications have been minor and easily resolved.

5. Pyelonephritis and severe hyperchloremic acidosis seen frequently after uretero-sigmoidostomy have not been eliminated by implantation of the ureters into an isolated segment of ileum but the incidence of these complications at a clinical level appears to be decreased.

The Measurement of Spasticity

Description of a Method and Evaluation of a Drug: Trancopal

FERNANDO TORRES, M.D.
BERNARD SANDLER, M.D.
TRUDY DE TORRES

Minneapolis, Minnesota

From the Division of Neurology, University of Minnesota Medical School and Hospitals, Minneapolis, Minnesota.

SPASTICITY is a challenging problem in the treatment of many diseases involving the central nervous system. A large number of drugs have been tried and only partial success has been obtained with any of them. Neurosurgical procedures have been devised to interrupt pathways which might facilitate spasticity. So far neither medical nor surgical management has proved effective.

A new drug, Trancopal,® 2-(4-Chlorophenyl)-3-methyl-4-metathiazanone-1-dioxide, has shown promising results in animal experiments and also in clinical trials on patients with muscle spasms. The experiments in animals showed evidence of inhibition of "polysynaptic" reflexes. Therefore, it was our hope that it would prove beneficial in patients with spasticity. A preliminary clinical evaluation gave us the impression that the drug produced good to excellent results in four out of five patients with spasticity produced by multiple sclerosis.

The evaluation of spasticity solely by clinical means may have its merits and gives us a "clinical impression." The only data, however, which are amenable to accurate comparison are those which can be subjected to statistical analysis.

Electromyography has previously been used as an objective method for evaluation of spasticity.[1-3] It is generally accepted that electrical activity recorded from spastic muscle during voluntary motion or during reflex action is increased in duration and area of distribution as compared with that of normal muscles. However, exact measurements of EMG spike amplitudes are difficult and may be influenced by instrumental variables and limitations. Furthermore, there is a large subjective factor in measuring the amplitude of muscle spikes, and finally, variations of the stimulus applied to the muscle are difficult to avoid.

Several mechanical and electronic machines have been devised for quantitative measurements of spasticity and rigidity. Some measure the resistance exercised by a limb when it is passively moved[4,5] and others try to assess the resistance of a limb to the force of gravity.[6] Although these methods are ingenious and useful, they are too elaborate for routine use.

In view of the aforementioned factors, it was

considered necessary to look for a new simple method to measure spasticity which would be amenable to statistical analysis. In this paper such a method will be described as it was used in the evaluation of Trancopal.

Definition of Terms

Spasticity.—". . . . Increased resistance to manipulation, hyperactive deep reflexes, and clonus . . . constitute spasticity."[7] Clonus, as clinically measured, however, is not always present in association with spasticity and it is only apparent in the more severe cases. On the other hand, some degree of impairment of muscle power is always present in clinical cases of spasticity.

Stretch or Deep Tendon Reflex.—Stretch or deep tendon reflex may be defined as the reflex contraction of a muscle in response to a sudden stretch applied to it.

Muscle Power.—When we speak of muscle power in this paper, we are referring to the *voluntary* control of a muscle as it is manifested by both the active movement of a limb and its resistance to passive motion. It is important to remember that in spasticity there is increased resistance to passive motion. This, however, is not a voluntary opposition, but is the result of a reflex contraction of the muscle in response to stretch. Clinically it is almost impossible to distinguish between the resistance to passive motion produced by voluntary contraction and that produced by reflex contraction. We have to rely on what the patient tells us in cases where there is no voluntary contraction exerted. On the other hand, when the patient is told to oppose passive motion, it is not possible, even for him, to tell how much is produced by his will and how much is caused by reflex. A muscle which is ineffective in performing voluntary movements should be, therefore, graded in a low category even if resistance to passive motion is good. Isotonic contraction is, thus, more reliable than isometric contraction for the assessment of muscle power.

Material

Ten patients from the University of Minnesota Hospitals Multiple Sclerosis Clinic were selected for this study. The group consisted of six women and four men. All had been classified under the diagnosis of "multiple sclerosis" and all presented spasticity of the lower extremities, ranging in degree from mild in one patient to marked in eight, only one presenting a moderate degree. The youngest patient in the group was thirty-three years old and the oldest fifty-two. Duration of the illness ranged from six to twenty years. The disease had been characterized by remissions and exacerbations in eight patients and had been slowly progressive in two. Of the eight who had history of remissions and exacerbations, five had remained stable in their symptoms for at least two years, one for less than one year, one showed slight continuous progression, and one had come out of the hospital three months prior to the start of the experiment. This patient had an exacerbation followed by rapid partial remission and was stable when the tests started.

Fig. 2. Rebound occurring when the leg reaches the vertical position. Note that it does not swing beyond this position, differing in this from pendulousness of a relaxed extremity.

Fig. 3. Pendulous swinging of a relaxed extremity.

Five of the ten patients had been treated with muscle relaxants, including Zoxazolamine,® Mephenesin,® and quinine sometime during the course of their illness. Although some had reported temporary improvement with one or more of these drugs, no one had obtained a sustained effect from any of them.

These ten patients were selected for this study because they showed spasticity of the lower extremities, because their disease had a long duration and was fairly stationary and because, in spite of their disability, they were able to appear for weekly examinations at the clinic. For this reason, patients who lived in the city were selected.

Method

All patients were told that a new drug for spasticity was going to be tried on them for a period of two months following one month of weekly examinations without receiving the drug. The examiners knew there were two compounds, designated compound "A" and compound "B," one a placebo and the other Trancopal. Both compounds were identical in appearance, and the examiners were unaware which was Trancopal. The hospital pharmacy gave either compound according to prescription of the examiners who specified one of the two ("A" or "B") and the amount of it calculated for one month for each patient at each time.

Examinations were carried out weekly on the same day of the week and at the same hour of the day. The first month the patients did not receive any drug. This period was used to obtain a picture of fluctuations of spasticity in each patient without the pharmacological or psycholgical influence of a new drug.

In the second month, five of the patients received compound "A" and the other five received compound "B." The doses were given so that those patients taking the active drug would receive 100 mgm. of it four times per day. The patients believed they were all receiving the medication at this time. Examinations were continued in the same way at weekly intervals.

In the third month, the patients who had received compound "A" were given a new prescription, this time for compound "B." Patients who had been taking "B" were switched to "A." Examinations were continued at weekly intervals without change.

The weekly sessions included three parts for each patient. First, the patients were questioned as to how they felt in comparison with the previous week regarding their general condition and, in addition, specifically if there were any changes in spasticity and muscle strength. The second part consisted of a clinical evaluation of muscle strength in both quadriceps and patellar tendon reflexes bilaterally.

Muscle strength was graded as follows:

0 = Absence of any voluntary movement.
1 = Contraction of muscle detected by palpation but without effect on the limb.
2 = Voluntary movement present but not possible against gravity.
3 = Voluntary movement against gravity.
4 = Voluntary movement against mild resistance applied by the examiner.
5 = Voluntary movement against strong resistance and contraction maintained unchanged in spite of sustained opposition; normal muscle strength.

Minor changes between one state and the next were found, and therefore shorter steps were added by a — or + sign in front of each number, except numbers 1, which had no — and 5, which had no +. Thus, there was the possibility of 13 grades of muscle strength. However, + and — were not used frequently.

Patellar reflexes were graded as follows:

0 = Absent
1 = Hypoactive
2 = Normal
3 = Hyperactive
4 = Sustained patellar clonus

Intermediate grades were indicated by adding + or —. Unsustained clonus was signfied by 3+ or 4— according to its duration.

The third part of the examination consisted of the application of our method for measuring spasticity.

For this part, the patient sat at the edge of a high table with both legs hanging freely. The lower limb to be examined was then completely extended passively at the knee. The foot was sustained by the examiner and the patient was told to relax his muscle as much as possible. When the quadriceps was completely relaxed as assessed by palpation of the muscle, the examiner suddenly removed his hand from under the patient's foot and let it drop freely. The whole procedure was previously explained to the patients and they were told to let the leg fall without voluntary interference.

The procedure was filmed each time with a cinematographic camera at a constant film speed of 24 frames per second. It was performed twice for each leg at each examining session.

The number of film frames was counted between the first frame that showed any movement of the leg at the beginning of the drop, and the first frame that showed the leg swinging beyond

the vertical position (Fig. 1). In many cases there were several rebounds towards the horizontal, before the leg had reached the vertical position (Fig. 2). In those cases, the frames were added until the leg came to rest in the vertical position or until it swung beyond this position, indicating that the quadriceps was completely relaxed. These repetitive contractions of the muscle may be interpreted as equivalent to clonus and clearly have different significance from the pendulous swinging of a relaxed leg (Fig. 3).

At the end of the experimental period, the data were tabulated for each examination, still without knowledge as to which of the two compounds administered was the drug and which the placebo.

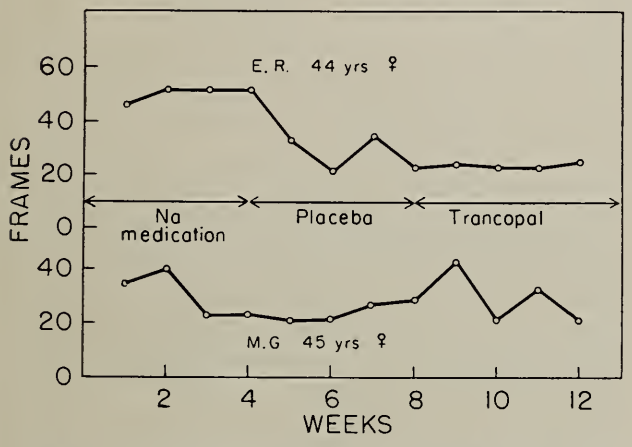

Fig. 4. Two types of curves in two patients who received placebo and Trancopal in the same sequence.

Results

When the numbers of film frames for each day of examination were put together in the form of graphs, very irregular curves were obtained (Figs. 4 and 5). On visual inspection, however, some curves seemed to show a descending trend.

For statistical analysis, we decided to use only the data obtained on the second trial of the right leg each week. It was felt that in this way, although the number of available data became more restricted, we would avoid artificially combining data for the two extremities or averaging the two trials for one given leg. The variations were quite large between the two legs and sometimes between two trials for one leg. This variability was remarkable even on patients whose disease process seemed fairly stationary.

Patients were divided into groups which we called "A first," and "A second," according to the period, second or third month, when they received compound A. Each group was subdivided into two columns of data, one column corresponding to the total number of frames of film obtained on the second trial with the right leg while the

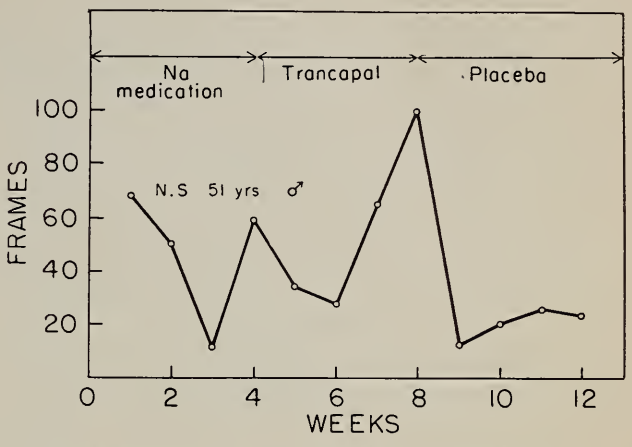

Fig. 5. A third type of curve in a patient who received the placebo and the drug in inverted order.

patient was on compound A, and the other to the number of frames while on compound B (Table I).

In order to find any significant difference between columns, we applied the formula:

$$t = \frac{\text{difference of means}}{\text{standard error of difference}}.$$

We first compared columns A and B of group "A first" and then columns A and B of group "A second." In this way, we looked not only for a significant difference between the columns which would depict different results between placebo and active drug, but also any difference that could be due to the sequence in which the two compounds were administered. We then compared column A of each group with the values obtained in the given group while the patients were not taking either compound ("O"). This should detect any significant changes produced by the psychological effect of a drug.

The results are shown in Table I. There was no significant difference between means in any of the instances investigated ($P = .1$). Thus there was no significant effect from the drug. We may say, on the other hand, that psychological factors did not influence the results with our method of testing spasticity in this group of patients.

From Table I, we may also say that there is no improvement with learning on the part of the

patients since there is no significant difference between the means of the three test priods.

In order to gather some statistical evidence which would make us feel more confident that what we are testing with our method is indeed spasticity as defined previously, we looked for correlation between reflex changes and number of frames, and also between muscle power and number of frames. If there is a direct relationship between degree of spasticity and number of frames of film, we should be able to predict that there should be a positive correlation between number of frames and degree of activity of deep tendon reflexes.

The correlation coefficient obtained from the total data on frames (second trial with right leg) and the total data on reflex activity on all the patients is r = .275. This indicates a positive correlation which is statistically significant (P = .01).

Six of our ten patients insisted on continuing the medication after the end of the experiment in spite of the fact that they were told that no significant effect on spasticity was obtained. They claimed that, in general, they felt better, slept better, and had less contraction spasms. This is possibly attributable to a "tranquilizing" effect which has been reported in connection with this drug.[8]

Correlation of degree of spasticity as measured by the method described in this paper, with deep tendon reflexes and muscle power, tends to corroborate the impression gained from theoretical considerations about the validity of the method.

In fact, we are measuring resistance to passive motion when the weight of the leg pulls on the quadriceps and at the same time we are measuring the response of the muscle to a sudden stretch. In this way, the two main properties of spasticity are involved.

The clinical methods for measuring strength and deep tendon reflexes may be crude and not as accurate as measurements by means of special devices. It is important, however, to restrict the number of our variables to one; the one that is being evaluated. The clinical examination of neurological functions has given us the values that we use in the daily definition of symptoms. Therefore, when we describe a new method, we should test it by its degree of correlation with the known and established values. If our method is valid, there should be a significant correlation. This correlation should not be too high, however, if the new method is more accurate than the old clinical techniques, as we assume it is. If the correlation is very high, we would have to conclude that the accuracy is of similar degree.

Decreased muscle power is said to be associated with spasticity. Therefore, we looked for a correlation between muscle power, as clinically measured and graded as previously described, and number of frames of film. The correlation coefficient is —0.384, which is statistically significant (P.= .01). There is, then, a significant negative correlation between spasticity, as measured by the method described in this paper, and muscle power, as clinically assessed.

Subjective evaluation of the drug by the patients did not present a consistent pattern. Some felt no improvement at all, some felt better while they were taking the placebo, some felt better while they

were taking the medication, and some felt better during the last two months of the experimental period while they were getting some "medication."

Side effects from the medication were completely absent except for slight somnolence in one patient. Urine analyses, blood counts, and liver function tests have been performed by us in patients on Trancopal four months or more and no abnormalities were found.

Discussion

From our data, we conclude that Trancopal did not produce significant effects on spasticity. This lack of response may be due to insufficient doses and not necessarily to aboslute lack of effect. Since we started the experiment, much higher doses have been given by other authors for varied conditions without any side effect.[8] We did not want to change the doses after we had started our testing period in order not to introduce new variables.

We found a positive correlation between the number of frames of film and activity of stretch reflex, and a negative correlation between the former and muscle power. Although some have the clinical impression that a spastic muscle is not weak and that when spasticity is overcome by some treatment the muscle becomes weak, this does not seem to be the case. According to our results, the more spastic a muscle is, the weaker it is. It is probable, however, that if we eliminate spasticity in a given case, even though muscle power may improve at the same time, it does not improve enough to give a normal function. With disappearance of spasticity, the hyperactive stretch reflexes will disappear and so will the increased resistance to passive motion. These two factors acting in the lower extremities in spastic patients, the first predominantly in antigravity muscles, make the limb *more effective functionally,* in a given *abnormal* condition. But this does not authorize us to say that the limb is stronger since the voluntary power is not increased but diminished in patients with spasticity.

Our method is based on the "pendulousness test" described by Wartenberg.[9] We have supplemented it by using cinematography for making it a quantitative method which is easily amenable to statistical analysis. Furthermore, we only use the first phase of the pendulousness test and observe only the fall of the limb to the vertical position. In fact, our measurement ends when pendulousness starts.

Recently Boczko and Mumenthaler[10] used photography to evaluate pendulousness and analyze changes in its duration and type. We believe that our method is more strictly quantitative and more accurate because it is less susceptible to influence of subjective factors. At the speed of film that we used, a large number of frames is exposed in most cases, and therefore small variations in counts which may occur between two different observers are of little relative significance. Cinematographic record of the passive motion of a limb is not only an accurate way for quantitative measurement of spasticity, it is also an appropriate method for frequent, short interval observation of the behavior of that limb as it goes through passive motion. This application should be useful in the study of pathophysiological mechanisms of spasticity.

Summary

A quantitative method for evaluation of spasticity is described. This measures by means of cinematography, the time of fall of the leg from the horizontal to the vertical position. The frames of film exposed during the time are counted and the changes in number subjected to statistical analysis.

The method was applied to the evaluation of a new drug, Trancopal, being used in patients with spasticity from multiple sclerosis.

Although there was no significant difference in effect on spasticity between a placebo and the drug under investigation, the majority of patients insisted in continuing taking Trancopal at the end of the experiment. In general, they felt better. This is attributed to the tranquilizing effect of this drug.

Positive correlation was found between spasticity as measured by this method and degree of hyperactivity of deep tendon reflexes. There was a negative correlation between the former and clinically measured muscle power.

The results are discussed.

Acknowledgment

We wish to express our appreciation to Dr. Eugene Johnson from the School of Public Health of the University of Minnesota for his cooperation in the statistical analysis. Also to Miss Sara Kugler for her technical assistance.

Winthrop laboratories supplied the Trancopal and the placebo tablets for this study.

Demerol as an Anesthetic Agent

SINCE THE use of intravenous Demerol® as an adjunct to anesthesia was first reported,[1] many investigators[2-7] have testified to its safety and efficacy in various surgical procedures. Such reports attest to ever increasing evidence that the traditional objections to the use of a narcotic in the operating room are unfounded. At the Asbury Methodist Hospital in Minneapolis, Demerol is routinely used as a primary anesthetic agent. Observations on 9,000 patients in whom the drug was so employed form the subject of the present report.

The cases included in this study were chosen consecutively from individuals undergoing major surgical procedures and selection was in no way limited by the type of operation, physical condition, age of the patient, or operative risk. Demerol was used in all cases for both induction and maintenance of general anesthesia. This project began in August, 1954 and is still in progress.

Methods and Results

A uniform method of induction was established for all adult patients: an initial dose of 100 mg. Demerol was administered intravenously followed by inhalation of a 2:1 mixture of nitrous oxide-oxygen. A combination of Pentothal® Flaxedil® was added until induction was complete. Demerol was then administered in increments of 20 mg. every four to ten minutes to maintain the desired surgical plane of anesthesia. Thereafter Pentothal, Seconal® or Flaxedil was added in small quantities when necessary. Intubation was performed when indicated and in these cases respiration was controlled for the remainder of the procedure. During or immediately following the closure, Demerol was discontinued and pure oxygen administered until the patient demonstrated an adequate respiratory pattern.

Children were treated similarly, with appropriate modifications in dosage as determined by age and weight.

The total dosage of Demerol varied considerably with the surgical procedure, the age and the weight of the patient. The smallest amount was given to a thirty-hour old infant during enucleation of one eye and iridectomy of the other for congenital bupthalmos and simple glaucoma, respectively. The largest dose was given during a sub-total gastrectomy performed on a forty-six-year-old negro male weighing 227 pounds. During this procedure, which lasted eight hours and twenty minutes, the patient received 2230 mg. of Demerol.

Table I shows the variation in dosage of Demerol in five typical surgical procedures.

Anesthesia was satisfactory and well maintained during all procedures, and complications during the postoperative period were found to be minimal. After discontinuation of Demerol, spontaneous respiration generally occurred within a

short period of time and never exceeded twenty minutes. The longest period before a patient became totally reactive (responded to instruction) was three hours.

Respiratory and cardiovascular disturbances occurred infrequently and respiratory depression severe enough to warrant the use of Nalline® was seen in only four patients. When hypotension did occur during surgery it served as a guide to circulating blood volume and enabled corrective measures to be taken which reduced the incidence of postoperative shock. Vasopressor agents were required in only five patients whose conditions were complicated by coronary artery disease and who were thus felt to need vigorous treatment for even minimal signs of hypotension.

In open chest procedures, there was a surprising absence of cardiac irregularities and in other general surgical procedures not one pulse irregularity was noted. Two hundred patients were followed by cardioscopic examination which revealed no evidence of abnormality.

Discussion

The danger of respiratory depression has been the main contraindication to the use of Demerol in anesthesia. There are numerous reports, however, which indicate that disturbances in respiration need not be a hazard. In a survey of 800 cases in which Demerol was administered intravenously by continuous drip as a supplement to nitrous oxide-oxygen anesthesia,[8] a gradual slowing of the respiratory rate was observed, the respiratory center remaining functionally unchanged unless high doses of Demerol were administered rapidly. These conclusions are supported by an earlier report[9] in which respiratory and circulatory changes were avoided if Demerol was given slowly. If respiratory depression does occur, prompt recovery is the rule.[10-12] Our findings tend to support these previous investigations and when mild respiratory depression did occur, it was used to advantage and facilitated controlled respiration. In only four patients was depression serious enough to require an antidote.

TABLE I.

Procedure	Average Dose of Demerol	Maximum Dose of Demerol
Appendectomy	200 mg.	460 mg.
Cholecystectomy	285 mg.	1000 mg.
Gastric resection	420 mg.	2230 mg.
Lobectomy	360 mg.	1100 mg.
Craniotomy	400 mg.	840 mg.

Demerol combined with nitrous oxide anesthesia has been found safe and convenient even for children and elderly patients in poor physical condition. Auld noted that children were in better condition during the operation and withstood long procedures better.[13] In our series of patients both the youngest, a thirty-hour-old child, and the oldest, a 101-year-old woman, recovered uneventfully from anesthesia.

The advantages of Demerol in reducing the amount of barbiturates required during anesthesia and in shortening recovery time are well documented.[8,14-18] When barbiturates are used alone, they must be given in large doses to induce unconsciousness. The risk of respiratory depression is great and recovery time is prolonged thus increasing the number of possible postoperative respiratory and circulatory disturbances. In Widdowson's paper[16] it was noted that recovery time was shortened by more than one half when Demerol was added to a nitrous oxide-pentothal combination. This observation, lends support to the results we have observed in other patients. Recovery of a normal respiratory pattern varied from one to twenty minutes, and the maximum total recovery time was three hours. Supplementation and maintenance anesthesia with barbiturates was minimal and only occasionally necessary.

The second important reported objection to the use of Demerol as an anesthetic drug has been its effects on the cardiovascular system in inducing hypotension and cardiac arrythmias. As has been previously stated, these effects were found to be negligible in our experience with intravenous Demerol. Other observers have reported similar findings. Johnstone,[9] in a controlled study, administered Demerol intravenously to normal subjects and found EKG patterns to be essentially unaltered, while Ausherman, Nowill and Stephen[8] found blood pressure, pulse pressure and pulse rate to be unchanged in patients receiving Demerol as an anesthetic agent.

At the conclusion of this study, it was our opinion that Demerol, used as the primary anesthetic agent, had in good measure been responsible for the absence of even one instance of cardiac arrest, or death in the operating room or recovery section.

Summary and Conclusions

1. Intravenous Demerol combined with nitrous oxide-oxygen was used to induce and maintain general anesthesia in 9,000 major surgical procedures.

2. Observations are discussed with particular reference to the effect of Demerol on respiratory and cardiovascular systems. The lack of any untoward effect upon cardiac regularity was particularly gratifying and was considered to be highly significant in a series of this size.

3. A comparison of findings with those of other investigators indicates that this combination is effective and safe in general anesthesia.

Dr. Kjenaas is Acting Clinical Director at Hastings State Hospital.

Dr. McHugh is Associate Professor, Division of Biostatistics, School of Public Health, University of Minnesota.

DURING the summer and autumn of 1956, we had the opportunity to carry out a small pilot study using promazine (Sparine*) in the treatment of patients with acute psychotic reactions admitted to a State Hospital. Like other phenothiazines, promazine appeared to be of value in the treatment of these acute psychotic reactions[1,2] and this together with favorable reports of its effect in chronic psychosis[3-6] encouraged us to try it in the treatment of more chronic schizophrenic patients. Aside from the impression of generally favorable effect, little information was gained from the uncontrolled pilot study. Rather large doses were used, twelve of the seventeen patients in the pilot study requiring doses of 1600 mg. a day or more. Five of these patients had grand mal seizures. Also, one patient in the pilot study developed a transient depression of the white count.[7,8] One patient in the pilot study experienced postural syncope when he reached a dose of 2400 mg. a day. Aside from these side effects typical of phenothiazines, no other toxicity or side

*Promazine Hydrochloride (and identically appearing placebo capsules) provided as Sparine by Wyeth Laboratories.

effects were apparent—such as photosensitivity, jaundice, or significant Parkinsonism.

The study reported herein (on the chronic group of patients) took place from April 1 to August 1, 1957, and involved sixty patients—thirty treated with the drug and thirty controls, with drug and placebo being administered in double blind fashion.

Method and Procedure

Description of Patients.—The sixty patients included in the study were selected from our chronic schizophrenic population on the basis of the chronicity and severity of their illness and the failure of response to prior therapies. (They were not broken down as to diagnostic sub-types in the schizophrenic category because it was not felt that this was of much value in such a chronic group.) Data was obtained on nine factors: ward, sex, age, duration of illness, and five prior therapies, namely, lobotomy, "conventional" electroshock treatment, insulin coma therapy, ataractic drugs, and "regressive" electroshock therapy (REST). Of these nine variables, four were experimentally controlled: ward, sex, prior lobotomy, and prior REST. The remaining five extraneous variables (age, duration of illness, and the other three prior therapies), were statistically controlled by randomized allocation of patients to the drug and placebo treatments. The information on these variables is summarized in Table I.

Of the five prior therapy variables, prior lobotomy and REST were controlled experimentally for the following reasons: (1) lobotomy and REST were considered the most drastic somatic therapies and, therefore, more likely to leave residual effects that might influence the subject's response to drug therapy more than the other prior therapy categories; (2) lobotomy, in particular, represents a concrete permanent change in all patients involved that makes them *a priori* different from non-lobotomized patients; (3) the group having had REST all received this treatment three to nine months prior to this study and, as they were part of an experimental REST study, thus had received a uniform, well-defined treatment schedule; we felt this isolated them as a more or less pure subgroup, similar in kind to the lobotomy group; (4) the patients who had received insulin coma, conventional EST, or prior drug therapy, had received such varied quantities of these modalities and at such varied times in the past (from months to many years), that it was felt they were not sufficiently defined in subgroups to warrant isolation for study.

Dosage.—As noted in the introduction, five of twelve patients in the pilot study, who were on a dosage of more than 1600 mg. a day, developed grand mal seizures. Therefore, we decided to hold the maximum dose to 1200 mg. a day. However, four patients developed grand mal seizures, two to seven days after dosage level of 800 mg. a day was reached during the second and third weeks of the experiment. These patients were then lowered to a total dose of 400 mg. a day, while the remainder of the experimental subjects remained on the 800-mg. dose level.

Evaluation of Psychiatric Effect.—The chief method of appraising the psychiatric effect of drug and placebo was through the use of the L-M Fergus Falls Behavior Rating Scale.[9] This measuring device (hereafter referred to as the "L-M" Scale), was used for the following reasons: (1) simplicity; (2) previously demonstrated reliability[9]; (3) validity for evaluation of chronically ill, regressed patients[10]; (4) reasonably comprehensive samples of behavior; (5) quantifiability of results. Ten of the fourteen items on the L-M Scale were considered relevant in evaluating these chronically ill patients. The scale is a very simple one as can be seen from the sample item which follows. Low numbers indicate inadequancy of performance, high numbers indicate more normal behavior.

H. Attention to dress and person

1.———has to be dressed—needs special attention of one kind or another.
2.———dresses self, but is sloppy.
3.———some interest in looks—too much lipstick, fairly neat.
4.———cares about looks and dress. Will ask for makeup or shaving equipment.
5.———normal attention to dress and person.

Although the designers of this scale have published reliability data,[9] we also collected reliability data from this study. The agreement between two raters on a given ward was acceptable.

Evaluation of Toxicity and Side Effects.—The presence of extrapyramidal signs, seizures, and

clinical hepatic toxicity was determined by clinical observation. Blood pressure changes were evaluated as follows: during the second week of the study, after maximal doses had been reached, the blood pressures were taken three times daily for three days, in both supine and (immediately thereafter) the erect posture. These measurements were carried out about one hour after each of the first three doses of the drug.

In addition to clinical observation on hepatic toxicity, that is, the presence or absence of jaundice, the subject's urine was tested for bile every three weeks throughout the study. The presence or absence of granulocytic depression in the blood was detected by measurements of the leukocyte count every three weeks during the study.

Since this was a double blind study, all measurements were done on placebo and drug subjects alike, while the nursing personnel, laboratory technician, and physician (acting as observer) did not know which patients were receiving promazine.

Results: Psychiatric Effect

L-M Scale Results.—Six L-M ratings were obtained for each patient, one initial or pre-study rating and five subsequent ratings spaced over the four-month study. Thus, for each patient, five different scores can be derived; that is, subsequent rating minus initial rating. These were then analyzed.[11] As stated in the last section, the L-M is constructed so that higher raw scores indicate more normal behavior; hence, positive difference scores are in the direction of improvement, and negative scores in the direction of more severe illness. For example, in Ward C, from Table II it is seen that the placebo group had a negative average difference score of minus 3.1, whereas the promazine group averaged a plus 1.0.

Since the study was carried out on four different wards, with four different sets of raters, we have an opportunity for four independent experiments discussed below.

TABLE II. RESPONSE TO PROMAZINE AND PLACEBO
(Ward C, 23 Patients)

"Prior Therapy" Group	Promazine	Placebo	Estimated Effect	Standard Error
Prior Lobotomy	— .3	1.0	—1.3	1.8
Prior REST	1.8	—2.6	4.4	1.8
Neither	1.3	—4.9	6.2	1.1
Weighted Average	1.0	—3.1	4.1	.82

TABLE III. CHANGE IN RESPONSE TO PROMAZINE AND PLACEBO OVER PERIODS OF TIME
(Ward C, 23 Patients)

	Time Periods									
	I		II		III		IV		V	
Prior Therapy	Drug	Placebo	Drug	Placebo	Drug	Placebo	Drug	Placebo	Drug	Placebo
Prior Lobotomy	—4.5	2.5	—2.0	2.0	1.0	1.0	2.0	0	2.0	—0.50
Prior REST	1.5	—3.5	4.5	—8.5	3.0	0.5	2.0	—2.0	—2.0	+0.50
Neither	1.8	—6.0	0.6	—5.2	1.0	—4.2	2.6	—3.8	+0.32	—5.20

Ward C.—From Table II, it is seen that the over-all difference in effect of promazine and placebo averages 4.1. This effect is statistically significant (standard error, 0.82).

In addition to the over-all effect of the drug, there is a significant difference between the various "prior therapy" groups and their response to drug and placebo as illustrated by Table II. From this table we see that the presumed beneficial effect of promazine is most noticeable with the ten patients in the "neither" group (neither REST nor lobotomy) (average difference 6.2). The difference in the "prior REST" group is not so striking (mean difference 4.4), but here the placebo subgroup did not deteriorate as much as the "neither" placebo group.

Some light on the question of how the drug effects vary with time is available from Table III. Considering first the "neither" group, we see that the drug and placebo group maintain a fairly constant difference throughout each period, thus reflecting the over-all difference. In the case of the "REST" group, however, the favorable difference noted initially between drug and placebo are reversed at the last period (this is not enough to affect the over-all favorable difference previously mentioned). The results of the "lobotomy"

group, are quite interesting. Here, the drug group is initially quite inferior to the placebo group, but there is a consistent drift in opposite directions for the drug and placebo group, so that the trend is consistently favorable for the drug group (as previously noted, this favorable trend was not of sufficient magnitude to give an over-all favorable difference for the lobotomy group).

At this point we should pause for a bit of interpretation since the foregoing description of the L-M Scale findings on Ward C represent the only statistically significant psychiatric findings from this study. What do these results mean? Perhaps the most striking observation is that (particularly for the "neither" group) a large part of the observed differences were contributed by the deterioration of the placebo group from its initial level, and only a minor part of the difference was due to improvement in the promazine group. We do know that some of the patients from both drug and placebo group were on ataractic (especially chlorpromazine) drug therapy of variable dose and duration prior to the initial L-M. Since all such drugs were discontinued after the initial L-M and before the Period I measurement, we can speculate that the deterioration of the placebo group may have been related to this loss of prior drug therapy in a substantial number of the patients. The promazine was barely able to maintain L-M performance throughout the study, despite the fact that many of the patients had not been on prior drug therapy.

Wards A, B and D.—The L-M data for these wards was analyzed and charted in a similar fashion. The effect of the drug was not statistically significant in any case.

Results: Toxicity and Side Effects

Extrapyramidal and Related Toxicity.—The majority of phenothiazines so far used clinically are capable of causing extrapyramidal symptoms such as muscle rigidity, tremor, masked facies, and excess salivation. In our pilot study, we noted minimal signs of Parkinsonism even with doses of promazine in excess of 1600 mg. a day. In the experimental drug group, no unusual muscle rigidity or tremor developed. However, four patients receiving the drug (none in the placebo group) developed severe continuous excess salivation with drooling. One of these patients had also had a seizure and was only on 400 mg. per day; the others were on 800 mg. per day. Two of the four developed ulcerative stomatitis and the drug had to be discontinued, in one case during the fourth week, and in the other in the ninth week of therapy. White blood counts were elevated at the time of the stomatitis. All four of these patients were extremely regressed men—mute, negativistic, withdrawn, "immobile" in character, with severe habit deterioration.

Masked facies, as observed in classical Parkinsonism, could not be defined. However, many patients were noted to have ptosis of the eyelids. This was mild, symmetric, and inconstant. The subjects with ptosis were identified and recorded in the third week of the study, and again in the fourteenth week. Both sets of observations were done in the early evening after the patients had received three of the four doses of drug or placebo for that day, and the second set of observations in the fourteenth week was done without reference to the first set. Upon completion of the study, this information was analyzed[12] to see how accurate the observer was in identifying the drug patients on the basis of the presence of ptosis. It was concluded that the observer did a better job in identifying patients on thed rug early in the study than he did later, perhaps because ptosis lessens as tolerance occurs.

Hepatic Toxicity.—Since jaundice of intrahepatic obstructive type has been observed with Chlorpromazine, we incorporated a screening test for urine bile in our study of promazine. Our laboratory used Smith's test for bile pigments.[13] About five out of eight patients receiving the drug were found to have bile in the urine (62 per cent, standard error 5 per cent). All of the control subjects gave negative results.

Similar positive reactions for bile in the urine have been reported for patients on Chlorpromazine and considered to be unrelated to hepatic dysfunction.[14] If this test could be refined so that it could be used as a simple semi-quantitative estimate urinary phenothiazine content, it would have practical value in a state hospital setting.

Hematopoietic Toxicity.—No clinically detectable effect on leukocytes was noted. One leukocyte count below 5,000 was obtained, but this was on a control patient. The more than 400 determina-

tions (seven for each patient) were analyzed by the same statistical methods used in analyzing the L-M Scale results. No statistically significant trends were noted indicating any difference between drug and placebo groups. This is not surprising in view of the small number of patients receiving drugs, and particularly the small number of female patients who are reported to be more susceptible than males to phenothiazine induced agranulocytosis.[7]

Grand Mal Seizures.—No patients known to have seizures were included in the study at the outset. Phenothiazines have been known to increase susceptibility to grand mal seizures, and studies correlating electroencephalographic changes with drug therapy have been done in patients receiving Chlorpromazine.[1,4,15,16] In fact, Chlorpromazine has been suggested as a means of "activating" the brain wave in patients suspected of cerebral dysrhythmias.[17]

Four of our thirty drug patients developed grand mal seizures, whereas none of the group receiving the placebo had seizures. All the seizures occurred in drug patients on Ward B and C. We first examined the data from the point of view of the occurrence of seizures while on promazine in relation to prior lobotomy because it is known that prior lobotomy at times renders the patients susceptible to grand mal seizures. In neither ward was a statistically significant relation found between the occurrence of seizures and prior lobotomy in the drug group.[18]

The data on Wards B and C were also analyzed for over-all statistical association of seizures occurring in the drug group. Although seizures occurred among those receiving the drug and not those receiving the placebo, the occurrence is within conventional chance levels for the stipulated dosage of 800 mg. per day.

Nevertheless, in view of the suggestive findings from the pilot study and reports in the literature, it appears that promazine hydrochloride therapy may be related to the occurrence of grand mal seizures. This appears particularly likely in view of the fact that none of the patients in either drug or placebo group have had further seizures up to the time of this report.

Postural Hypotension.—As described previously, nine pairs of blood pressure determinations (obtained supine and erect) were available for analysis. We were able to carry this program out on Wards A, C, and D only, and patients were unavoidably missed on occasion. Nine patients had one pair of readings missing and five had either two or three of nine possible readings missing. However, sufficient data for analysis was obtained on forty-one patients with interesting results. The effect of the promazine upon systolic blood pressure was examined for statistical significance. For all three wards, a greater proportion of drug than placebo patients had postural declines exceeding 30 mm. of mercury, in fact, significantly so.[18] It is, therefore, obvious that the possibility of postural faintness appears to be present in the drug group fairly frequently. In actuality, however, frank syncope was observed only once in the entire study.

Miscellaneous Observations. — The industrial therapist, who was also unaware of which patients were on the drug, was asked to prepare a report indicating change in industrial therapy assignment and his evaluation of performance. This was an area of patient activity which could not be fully reached by the psychiatric aide using the L-M Scale since the majority of industrial therapy assignments are off the home ward. The industrial therapist report indicated the following: (1) approximately the same number of patients in each group were on prescribed industrial therapy assignment, both at the beginning and at the end of the study; (2) according to his evaluation, an approximately equal number (about one-half) of treatment and control patients had "improved" in their industrial therapy assignment during the study.

Likewise, liberty status and home visit status in these patients did not significantly change during the course of the study. One patient was discharged who was on drug but the discharge was a placement on a work-farm and had been arranged prior to the study, and his inclusion in the study was erroneous for this reason. One patient was clinically observed to improve considerably during the course of the study although her L-M Scale did not reflect this improvement. She was started on Chlorpromazine at the end of the study, and discharged in fairly satisfactory remission three months later. This is the only patient discharged from the group during a one-year follow-up. This points up what a severely and chronically ill group these patients represent.

Summary and Conclusions

From April 1 to August 1, 1957, the phenothiazine derivative, promazine, was evaluated in a double blind study. Specifically evaluated were psychiatric effect, neurotoxicity, and hematopoietic and hepatic toxicity. The study concerned sixty chronically ill schizophrenic patients, eighteen women, 42 men, ranging in age from nineteen to sixty years. These patients were randomly divided into two groups (except as modified by blocking for ward and sex): the prior therapies—lobotomy and REST, and a group who had received neither of these therapies. A maximum dose of 800 mg. per day was used, except in the case of four patients who had seizures whose dose was maintained at 400 mg. per day. The following conclusions are drawn: The psychiatric effects of promazine in this dose for this group of patients was not clinically significant. In three of the four wards, including the ward for women, no statistically significant effect was observed (as measured by the L-M Scale). In Ward C, a male ward, statistically significant changes of a favorable nature were noted on the L-M Scale. This was especially true for the group who had received neither REST nor lobotomy. Despite this improvement in L-M Scale performance, no significant clinical benefit was noted in terms of detectable clinical change, change in industrial therapy status, or discharge potential.

Muscle rigidity, tremor, or masked facies were not noted. Excess salivation was observed in four treatment patients. In two of these, a severe ulcerative stomatitis occurred, which may have been coincidental, but appeared to be related to the excess salivation.

Grand mal seizures occurred in four patients on the drug, and in none of the placebo patients. However, this difference was not statistically significant.

Mild to moderate postural hypotensive effect was observed in many treatment patients, but syncope occurred in only one patient during the entire study.

Agranulocytosis, hepatic toxicity, allergic reactions, or photo-sensitivity were not noted.

Acknowledgment

The authors wish to express their appreciation to Dr. Wm. F. Sheeley, former Superintendent, and to the many staff members at Hastings State Hospital, Hastings, Minnesota. Their co-operation and support was essential to the completion of this study.

The Human Female: Anatomy of Sexual Response

The phases (excitement, plateau, orgasm, resolution) of woman's sexual response are described with particular reference to changes in breasts and pelvic structures.

WILLIAM H. MASTERS, M.D.
VIRGINIA E. JOHNSON
Saint Louis, Missouri

This investigation was supported in part by Research Grant RG-5998, Division of General Medical Sciences, Public Health Service.

From the Department of Obstetrics and Gynecology, Washington University School of Medicine, Saint Louis 10, Missouri.

SUCCESSFUL sexual stimulation of the human female initiates a generalized physiological response throughout the entire body. The present discussion of specific anatomical reaction will be confined to the primary and secondary organs of sexual response—the breasts and the pelvic reproduction tract. The response of the reproductive viscera is one of marked vaso-congestion, just as penile erection is vaso-congestive evidence of the human male's response to effective sexual stimulation.

Although penile erection is the primary response of the male to effective stimulation, the female exhibits multiple primary and secondary anatomical reactions during the varying phases of a complete orgasmic response cycle. Descriptive terminology has been developed by the Washington University Sex Research Project to delineate the female's sexual response cycle. This was found necessary in order that the reactions of the breasts and the pelvic reproductive organs to mounting sexual tension might be more effectively described from an anatomical point of view. It has become evident that many of the human female's definitive anatomical reactions to sexual response are fleeting, and frequently may be confined to only one of the four phases of the total orgasmic response cycle.

The human female's sexual response cycle has been arbitrarily divided into four separate phases.[1] These phases are, in order: excitement, plateau, orgasm, and resolution. The excitement phase may vary in length from a few minutes to a matter of several hours depending upon the intensity, and the continuity of the sexual stimulation techniques employed to develop the individual female's anatomical responsiveness. This first phase of the orgasmic response cycle is measured from the onset of any form of sexual stimulation (psychic or physical), until the human female enters her second or plateau phase of response. The plateau phase is generally a much shorter time reaction sequence, during which the female gathers physiological and psychological strength from the stockpile of mounting sexual tension, until she can direct all her physical and mental forces toward a leap into the third, or orgasmic phase of sexual tension expression.

The actual orgasmic phase may last from three to eight or even ten seconds in its entirety. Obviously, the more extended the orgasmic phase response, the more severe the physiological and anatomical reactions which have developed within the responding female's body. The fourth and final phase of the sexual response cycle, resolution, is roughly proportional in time sequence to the first or excitement phase. When a short excitement phase is followed in rapid sequence by plateau and orgasm, resolution in its turn will tend to be a short-lived affair. If, however, a lengthy excitement phase is followed only by plateau phase achievement at best, with no orgasmic phase relief, resolution from this unrelieved sexual tension level will inevitably develop into a lengthy and frustrating experience.

Breasts

When we consider the response of the breasts to effective sexual stimulation, the most notable development during early excitement phase is that of nipple erection. It is important to emphasize, however, that erection of breast nipples is not necessarily a response restricted to sexual stimulation alone. The breast nipples may undergo erection in cold weather, or subsequent to immersion in cold water. The erection phenomenon has frequently been observed upon the removal of an excessively binding undergarment, or subsequent to the continued pressure of sleeping in an abdominal position. There are many women who have inverted nipples incapable of erection; so this erection reaction is not a constant finding, nor when it develops is it confined alone to the excitement phase of sexual response. It is present throughout the entire sexual response cycle.

As tension mounts under any continued effective stimulation technique, the areolae (the colored areas of the breasts surrounding the nipples) become quite puffy or engorged. This engorgement reaction creates the false impression that the primary nipple erection has been lost. Actually, the areolae become so swollen that the erect nipple is partially obscured, and a false suggestion of loss of the nipple erection reaction is returned to the observer.

The breasts increase in size slowly by the process of trapping or slowing the venous blood flow until they are frequently noted to be from a fifth to a quarter increased in size over their basic norm, by the time the excitement phase has reached its terminal stages. In large breasts, this congestive increase becomes more noticeable. There are increased venous markings on the surface of the breasts early in the excitement phase, as the blood vessels become engorged with the slowed venous blood flow. After the excitement phase ends, and the plateau phase is established, a measle-like rash spreads from the upper abdomen over the breasts, usually appearing first on the inferior breast surfaces. During the remainder of the plateau and orgasmic phases, the development and spread of this measle-like rash is a characteristic of effectively applied sexual stimulation. This vasomotor phenomenon (sexual flush) is usually better demonstrated by the blonde or redheaded female than by one of brunette coloring. There is no particular breast response to the actual orgasmic phase of the sexual cycle. However, the sexual flush does reach its maximum spread as the orgasmic reaction phase develops.

As the resolution phase is experienced, the breasts return to their normal size in a slow involution reaction that is the direct reversal of the previously described excitement phase changes. First to disappear is the measle-like skin rash. Second to be lost is the increased breast size. The aerolae then begin to lose their engorged, swollen appearance. Finally, the nipples which have been almost hidden by the swollen aerolar area again appear to undergo an erection response. This is actually a false erection reaction. The erect nipples are simply the last evidence of sexual tension to leave the involuting breasts, after an orgasmic experience has released the venous engorgement developed during the first two phases of the complete sexual response cycle.

We might emphasize here a point of telltale evidence of effective sexual stimulation. As the human female is responding to sexual stimulation, the appearance of pink, granular rash may frequently be noted over the anterior chest wall and the breasts. A certainty of effectual sexual stimulation may be presumed, in the physiological response situation described. Unless the female is most adequately stimulated, she will not produce the measle-like rash (sexual flush) which is a true measure of the development of severe sexual tension.

The External Pelvic Anatomy

The response of the female pelvic reproductive anatomy to effective sexual stimulation may also

be described in relation to the four phases of the sexual response cycle. The external sexual anatomy includes the clitoris, the major and minor labia, and the Bartholin glands which are located on the inner aspect of the labia about two-thirds of the way from the clitoris to the posterior vaginal wall. The anatomical reactions of these target organs to sexual tension will be described in detail.

The clitoris is a small, sensitive organ consisting primarily of erectile tissue. It varies considerably in tissue content (generally about the size of a green pea), and is located on the antero-inferior surface of the large pelvic bone (the symphysis pubis) which runs across the front of both male and female pelves. The clitoris is covered by the folds of the labia (the prepuce) meeting in the midline just above the urinary outlet (the urethra). The prepuce protects the clitoris in the same manner that the foreskin protects the glans or head of the male penis. The clitoris and prepuce form the most universally erotic area of the female body.

As sexual tension mounts, the clitoris increases in size, but this response has great individual variation. Occasionally, the increase may be minimal. but frequently a two or three times increase in size has been observed. This response is another example of the trapping of venous blood flow by a target organ, developing subsequent to effective sexual stimulation. This small, sensitive organ has a tremendous blood circulation for its size. The increase in clitoral size is usually completed by the time the excitement phase has terminated.

No particular plateau or orgasmic phase response has ever been described for the clitoris. During the resolution phase the marked venous engorgement is lost very slowly. Frequently, the clitoris is the last of the pelvic sexual anatomy to return to normal size after a period of effective sexual stimulation. This is particularly true if the female does not attain the sexual tension relief of an orgasmic experience. Those women who experience long excitement and excessively extended plateau phases, and then must undergo an extended resolution phase without orgasmic relief, frequently take hours to lose the venous congestion of the organs of sexual response.

The major labia follow a relatively precise pattern of anatomical response to sexual stimulation. This reaction varies (as a general rule) with the number of children the individual female has produced. For the nulliparous female (no children), the major labia thin out and flatten upward and backward against the pelvic brim during advanced stages of the excitement phase. As the plateau phase is experienced, the major labia are, for all clinical purposes, a non-existent entity. However, for the multiparous individual (more than one child), particularly if there are significant labial varicosities present, the labia majora increase in size from two to three times, as the usual venous engorgement reaction develops. Then, the labia hang like the folds of a heavy curtain about the vaginal outlet. There is a tendency (even for markedly engorged, multiparous labia) to spread laterally as the plateau phase is anticipated, making the vaginal outlet more available to the mounting process. Again, as with the clitoris, there is no specific plateau or orgasmic phase response from the major labia. Resolution, with return to normal anatomical position and size, occurs more rapidly for the nulliparous than for the engorged, multiparous labia.

The anatomical response of the minor labia to effective sexual stimulation has been of particular interest to investigators. The unique sexual response of this target organ has been dubbed the "sex-skin" reaction of the human female.[1] Comparison has been drawn to the labia of the monkey bitch in heat.[2] The response of the monkey bitch (when ready to receive the male) is one of muted red discoloration of the entire vulval area. During the human female's excitement phase, the minor labia increase in size from two to three times their normal thickness, and extend laterally to provide additional support along the axis of the lateral vaginal walls. This reaction actually develops an additional centimeter or centimeter and a half of effective coital length for the vagina. The exception to this additional support is, of course, along the immediate posterior vaginal wall.

After the plateau phase has been achieved, there is a marked color change in the minor labia. Again there is variation with the parity (number of children) of the individual human female. The minor labia of the nulliparous female may turn a cardinal red, as the plateau phase advances. The minor labia of the multiparous female (particularly if there are marked vulval varicosities) may turn almost a burgundy-red instead of a cardinal color. These color changes are always evidence of an impending orgasmic experience.

If the individual female moves from the excitement to the plateau phase, and then unfor-

tunately does not achieve the sexual tension release resulting from a completed orgasmic experience, the color changes just described for the minor labia do not occur. If, however, the minor labia change color during an established plateau phase, and if the effective sexual stimulation techniques that have brought about these color changes are maintained, the human female will always undergo an orgasmic experience. In other words, once the minor labia establish the color changes of severe sexual tension, an orgasmic experience is not only imminent, but is sure to occur, if the particular sexual stimulation techniques are maintained. Usually, from the onset of the color changes described for the minor labia to the onset of the actual orgasmic phase response, only sixty to ninety seconds are consumed.

There is no particular anatomical reaction for the minor labia to the actual orgasmic experience. The resolution phase is again the complete reversal in anatomical sequence from the excitement phase. In other words, the first anatomical change of the resolution phase is for the minor labia to lose the sex-tension discoloration. Then the minor labia lose their vascular tension (increased size), and return slowly to normal positioning and size.

The Bartholin glands secrete a mucoid type of material under the influence of effective sexual stimulation. It has been previously believed,[3-7] that this is an early excitement phase response to sexual stimulation. But these conceptions are in error. The Bartholin glands do not secrete during the excitement phase of the sexual response cycle unless it is maintained for a markedly extended time sequence. The usual onset of glandular secretory activity is during the plateau phase of female sexual response. The material liberated is at most three or four drops from either Bartholin gland. There is no particular orgasmic phase response, and the short resolution phase reaction simply consists of cessation of secretory activity.

The Internal Pelvic Anatomy

The internal pelvic anatomy of the organs of reproduction consists of vagina, cervix, uterus, fallopian tubes and ovaries. As yet, nothing is known of actual anatomical response of the tubes and ovaries to the influence of sexual tension. The anatomical reactions of the vagina, cervix, and corpus to sexual stimulation will be described in detail.

Probably the first definitive anatomical response of the entire female body to sexual stimulation develops within the vagina. Within ten to twenty seconds after the onset of any form of effective sexual stimulation, the vagina begins its well-known process of lubrication. Previously, it was believed that lubrication of the vagina either came from the Bartholin glands, or was the result of cervical mucous secreted by glands within the cervical canal.[8-14] It is now well-established that the lubrication of the vaginal barrel comes from the walls of the vagina itself[1] despite the fact that there are no secretory glands within the walls of the vagina.[15] Therefore, the actual anatomical source of the lubricating material is still in question, as are the biological properties of this unidentified material. However, the actual physical mechanism of vaginal lubrication has been repetitively observed, and may now be described in effective anatomical detail.[16]

Almost immediately after the onset of sexual stimulation, the vagina develops what has been termed "the sweating-phenomenon."[1] On the vaginal walls appears a glistening material which follows in general the pattern of a transudate reaction. This material is of such consistency that it changes the normal acidity (pH) of the vagina.[16] When it first appears on the walls of the vagina, one is reminded of a "sweat-beaded" forehead. Within short order, these droplets of lubricating material coalesce to form the well-lubricated vaginal barrel, which connotes advancing sexual tension. This lubrication phenomenon obviously develops very early in the excitement phase of any cycle of sexual response, and is present in varying degree whether or not the subject actually achieves orgasmic satisfaction. The resolution phase reaction is simply one of cessation of the secretory activity. However, the lubricating material has been demonstrated on collapsed vaginal wall surfaces two to three hours after completion of a successful sexual response cycle.

During the more advanced stages of the excitement phase, a consistent anatomical reaction develops within the inner two-thirds of the vagina. There is marked expansion not only in depth, but in width of the lateral walls of the vagina with mounting sexual tension. The ballooning of the vaginal walls increases the width of the inner two-thirds of the vagina from two to three times the unstimulated width. The length of the vagina is increased from two to four centimeters depending upon previous childbearing experience. This

increase of length and width occurs within the vagina as the result of a jerky, arrhythmic display of expansive force without any reproduceable pattern. This evidence of muscular activity occurs independently from the basic vasocongestive reaction to mounting sexual tension. The vaginal expansion reaction is essentially concluded by the time the plateau phase is reached. Thereafter, there are no further significant changes in the inner two-thirds of the vagina during the remainder of the sexual response cycle.

During the plateau phase, the vaginal responses are confined to the external third of the vagina. Here a marked vasocongestive reaction develops. The entire vaginal canal is congested to such a degree that the circumference of the outer third of the vagina is constricted to a third or a half of its previous excitement phase distension. The congested outer third of the vagina has been termed the orgasmic platform.[1] This orgasmic platform only develops as the plateau phase progresses. Once formed, however, it demonstrates the only significant vaginal reaction to the actual orgasmic phase of sexual response. During the orgasmic experience, the platform created in the outer third of the vagina by marked congestion of venous blood flow actually contracts with a recordable rhythmicity. The timing sequence essentially corresponds to the contraction of the male penis with actual ejaculatory effort (the male orgasmic experience). The orgasmic platform contracts from four to ten times in regular rhythm with approximately eight-tenths of a second between contractions. The more platform contractions noted, the more severe the orgasmic experience.

During the resolution phase, the first evidence of loss of target organ venous congestion is that of the orgasmic platform. The engorged outer third of the vagina rapidly shrinks back to normal size after orgasmic experience. Although the detumescence is not quite as rapidly completed as is the loss of penile erection after the male ejaculation, the orgasmic platform disappears within sixty to ninety seconds after orgasmic phase relief of sexual tension. The expansion of vaginal depth and width which developed during advanced stages of the excitement phase slowly involutes. Frequently, it takes five to eight minutes for the vagina to return to its normal unstimulated measurements. Vaginal lubrication activity ceases with orgasmic expression, although the lubricating material may be demonstrated on the walls of the vagina for an hour or two after completion of the cycle of sexual response.

The only remarkable cervical response to sexual stimulation is movement in conjunction with the reaction of the entire uterus. There is no secretory activity from the cervical glands at any time during the entire cycle of sexual response.[1] The cervix is pulled back and away from the vaginal outlet and upward toward the false pelvis, as part of total uterine movement during advanced excitement phases. This observed withdrawal of the cervix from the vaginal axis occurs at the same time that the vagina expands in width and depth. There is no characteristic response of the cervix to the plateau phase of sexual excitement. Immediately subsequent to orgasmic experience, a slight patulousness (opening) of the external cervical os has been described.[1] Again, it is worth emphasizing that no secretory activity of the cervical glands has been demonstrated. With development of the resolution phase, the cervix drops down into the depth of the vagina as the vaginal barrel loses its distension. This return of the cervical os to the vaginal floor is subsequent to loss of vaginal wall vasocongestion, and the collapse of depth and width expansion.

The uterus is pulled upward into the false pelvis during the terminal stages of the excitement phase. This elevation of the uterus only occurs in those instances when the uterus is in a normal anterior position. If the uterus is in a retroverted position (resting posteriorly on the bowel, rather than anteriorly on the bladder), there is no elevation of this target organ and, of course, no concomitant withdrawal of the cervix from the vaginal floor. There has been no particular plateau phase response demonstrated for the uterus. However, during the orgasmic phase, there is a regular contraction sequence of the uterine wall.[18] This is similar to the established contraction reaction of the orgasmic platform in the outer third of the vagina. This anatomical indication of sexual tension release is particularly effective, and easily demonstrated in the pregnant uterus. The contraction of the uterus as an anatomical orgasmic phase response may well be one of the real causes (in susceptible individuals) for multiple pregnancy loss, particularly during the first three months after conception. Uterine activity during the resolution phase parallels the pelvic relaxation reaction. There is a return to normal uterine posi-

tioning as the vaginal walls collapse. The muscular control of the withdrawal reaction of the corpus into the false pelvis, as sexual response develops, is not at present completely understood.

It is obvious from the recent demonstration of muscle tissue in the sacrouterine ligaments,[17] that these ligaments may well play a part in the elevation of the cervix and corpus. The base of the broad ligaments (Malencrodt's ligaments) are also suspected as playing a major part in the elevation of the lower uterine segment while the vagina expands in width and length under the influence of increasing sexual tension.

From the brief anatomical descriptions of the responses of the reproductive organs to effective sexual stimulation, it will be noted that the primary reaction is one of marked slowing and trapping of local venous blood flow. It should not be presumed however, that the only anatomical responses to sexual stimulation are confined to the obvious target organs. Far from it, really. The human female responds as a total body unit to effective physical and/or psychic sexual stimulation.

Although limitations of space do not permit detailed descriptions of the human female's generalized body reactions to sexual tension, a few selected examples are in order. For example, the measle-like rash (sexual flush) which appears over the surfaces of the breasts, during the plateau phase of sexual tension response, is by no means confined to the breast surfaces. As a matter of fact, this rash first appears over the upper abdomen and the diaphragm areas, then spreads to the breasts. This flush may also be noted over the arms, face, back, buttocks and thighs as severe tension reactions develop during the terminal portions of the plateau phase of the cycle of sexual response. This generalized flush rapidly disappears early in the resolution phase provided orgasmic tension release has been experienced. If no orgasmic experience has been enjoyed, the flush disappears at a significantly slower rate from the body surfaces.

The actual orgasmic experience is enhanced by generalized muscular contraction patterns far beyond the rhythmic contractions of the previously mentioned orgasmic platform and the uterus. The external rectal sphincter contracts in complete rhythm with the orgasmic platform during severe, orgasmic phase responses. Many other muscle groupings, too numerous to mention here, develop a spastic contraction state throughout the entire pelvis and the lower abdomen, as the individual reaches for orgasmic relief of her unendurable sexual tension. Even the musculature of the neck, hands, arms, feet and legs have their own individual spastic contraction pattern response to effective sexual stimulation.

The corded neck muscles, the swollen flushed face, and the expanded rib cage are familiar pictures of total female sexual tension response. In brief, the female target organs respond anatomically just to the degree that the total female is sexually stimulated. The more effective the sexual stimulation techniques are for the individual woman, the more complete her total body response is to the physiological and psychological demands for sexual tension release.

Ovarian Dermoid Cyst Complicating Pregnancy

From the Fritsche Clinic, New Ulm, Minnesota.

P. J. KITZBERGER, JR., M.D.
New Ulm, Minnesota

DERMOID CYSTS constitute about 10 per cent of all ovarian tumors.[1] They may occur at any age period, and about 25 per cent are bilateral.[2] These tumors when removed, are usually the size of a man's fist, are slow growing, and possess a marked pedicle which is liable to undergo torsion. Pathologically, these tumors are a form of teratoma and are supposed to arise not from the original ovum, but from one of the blastomeres formed by primary segmentation of the fertilized ovum becoming separated and included in the ovary.[1] The exterior of the tumor is smooth, and glistening, and the interior is filled with a yellow, greasy, buttery material frequently containing wisps of hair, teeth, bones, cartilage, skin, brain, and occasionally striated muscle and thyroid tissue. The tumor itself is almost always benign although it has been reported that some of the epithelial elements may undergo malignant change.

The problem of these cysts can be potentially serious if they are undetected during term labor, as it is quite feasible that a large dermoid could become incarcerated in the posterior cul-de-sac and obstruct the pathway of normal delivery.[3] The tumor could burst, setting up a fatal peritonitis, or it could undergo torsion with subsequent necrosis.[4] Sometimes smaller cysts are drawn out of the way during pregancy and these seldom cause symptoms unless they are severely bruised. When patients are seen within the first five months of pregnancy and an ovarian dermoid is diagnosed, pelvic laparotomy should be done and the cyst removed. If the tumor is detected late in pregnancy, the management should be altered and caesarean section, near term, is advised with incidental removal of the tumor.[5] Any malpresentation of the fetus near term should make one suspicious of ovarian tumor as the cause of failure of engagement of the presenting part along with other causes such as placenta praevia, myomata, and cephalo-pelvic disproportion to mention a few.

Blackwell carefully analyzed data on 225 pa-

tients who had cystic teratomas or dermoid cysts of the ovary at the Mayo Clinic and found that in two cases, delivery was complicated by dermoids measuring 8 cm. and 9 cm. in diameter; in both cases mechanical difficulty was encountered. One patient required manual displacement of the tumor to allow the head to engage. The other required Caesarean section.[6] Batson reviewed 108 cases of ovarian dermoids and found that four cases were associated with full-term pregnancy and that three of these patients were sectioned because of the possibility of obstructed vaginal delivery or rupture. Curiously, in fifteen of the 108 cases studied, the diagnosis was confirmed by x-ray examination.[7] Thirty-one per cent of the dermoids removed at the Mayo Clinic in Blackwell's study revealed teeth microscopically and grossly, so that the finding of teeth in the x-ray picture should make the diagnosis almost absolute. Wilson reported a case of ruptured dermoid cyst during the twentieth week of pregnancy proved at laparotomy and followed by a very stormy bout of peritonitis. The patient recovered and delivered a live infant later at term.[8]

The following case history will illustrate some of these points.

Mrs. W. A., a nineteen-year-old primigravida was seen for the first time by the author on May 15, 1958. She gave the history that she was not certain as to the time of her last menstrual period, but thought it was in early January, 1958, or in December, 1957, and that her menses had always been irregular since their onset at age twelve. She stated that she felt fetal movements for about one month prior to her first visit. A general physical examination, including the usual laboratory work, gave negative findings, except for the presence of a gravid uterus which seemed to be at least the size of a seven months' gestation, and a fetus lying in the frank breech position. Pelvis examination revealed a marked fullness in the posterior cul-de-sac, and the cervix was high under the symphysis pubis barely visible with the use of a bi-valve vaginal speculum. The fetal heart was of good quality, and the patient had no other unusual symptoms. On June 10, 1958, a flat radiograph of the abdomen was taken after a repeat pelvic examination was performed, and a single fetus lying in the frank breech position was diagnosed along with abnormal calcification in the maternal pelvis. The flat radiograph was taken only because the author was uncertain as to the maturity of the pregnancy as well as to the possibility of the presence of a multiple pregnancy since the patient seemed more advanced in fundal height than the history and dates would have indicated. On closer inspection of the flat radiograph (Figs. 1 and 2), it became obvious that the pelvic mass was an ovarian dermoid. On July 8, 1958, consultation was obtained, a repeat vaginal examination was done, and in view of the roentgenogram, a definite mass in the left ovary was easily palpable and measured at least 12 cm. in diameter.

On August 6, 1958, at the Union Hospital, New Ulm, Minnesota, a low cervical Caesarean section was performed under local and light sodium pentothal anesthesia, and an active male infant weighing 7 pounds, 15 ounces was easily delivered as a frank breech presentation. The left ovary was excised, and this proved to be grossly and histologically a dermoid cyst containing sebaceous material, teeth, hair, bones and cartilage. It measured 10 by 12 cm. in size. The patient made a completely uneventful recovery and was dismissed from the hospital on the seventh postoperative day. The microscopic diagnosis was that of a benign dermoid cyst as interpreted by the late James McCartney, M.D., of the Department of Pathology, University of Minnesota Hospitals.

Summary and Discussion

The case of a nineteen-year-old primigravida with a large dermoid cyst complicating advanced pregnancy is presented. The findings of abnormal fetal presentation, questionable maturity or advancement of the pregnancy, abnormal x-ray findings with clear demonstration of teeth and bones, led to the diagnosis of this tumor and its ultimate management. Despite the widespread fear of the use of roentgenograms during pregnancy, it is self evident that in this particular case, an x-ray examination made the diagnosis quite simple. The differential diagnosis should include any cause of abnormal pelvic calcification such as calculi in an ectopic pelvic kidney, calcified myomata, lithopedion from a previous abdominal pregnancy, and of course, teratoma or dermoid cyst. As to future pregnancy in the case illustrated, it is thought that because of an ample gynecoid pelvis, adequate hemostasis and primary afebrile wound healing, a vaginal delivery, with careful observation during all stages of labor, should be allowed.

Acknowledgment

I wish to acknowledge the kind help given by Drs. Albert and Carl J. Fritsche in the management of this case.

The Continuing Challenge of Streptoccal Infections and their Complications

Medical Progress

These investigations were conducted, in part, under the sponsorship of the Commission on Streptococcal Diseases, Armed Forces Epidemiological Board, and were supported by the Offices of the Surgeons General, Department of the Army, Washington, D. C., by a research grant (H-1829 C2) from the National Heart Institute of the National Institutes of Health, Public Health Service, and by the Minnesota Heart Association.

LEWIS W. WANNAMAKER, M.D.
Minneapolis, Minnesota

Professor of Pediatrics, University of Minnesota, and Career Investigator of the American Heart Association.

THE remarkable changes in the natural history of many infectious diseases following the introduction of antibiotics can be fully appreciated only by those who have witnessed the change from beginning to end. Some diseases have virtually disappeared; others have been modified; still others have emerged as newly important entities. Not all changes have been for the good and not all have been dramatic. Among the most interesting changes are those which are subtle rather than dramatic. Some of the most fascinating observations concern the ability of certain organisms to escape extinction even though they are among the most sensitive to antibiotics.

The group A streptococcus is such an organism. Like the pneumococcus, it is exquisitely sensitive to penicillin. Yet it continues to survive, continues to result in widespread infection, and continues to lead to serious complications—acute rheumatic fever and acute glomerulonephritis.

The Problem in Minnesota

The problem of streptococcal infections and their complications is with us in Minnesota today. And, in spite of our antibiotic attacks, there is no indication that they will surrender any time in the immediate future. Indeed, this winter and spring has been one of the biggest streptococcal disease years Minnesota has seen in some time. Pharyngitis and tonsillitis of streptococcal etiology have been common in many communities, and in many sections of the state we have even seen the return of the red banner of streptococcal disease, scarlet fever. In conjunction with this upsurge of streptococcal infection, there has been an apparent increase in the incidence of acute nephritis, in particular, and most likely also in rheumatic fever. The common belief that rheumatic fever is dying out in Minnesota and elsewhere is due to the fact that no one physician sees very many patients with acute rheumatic fever among his patient population. This faulty impression is also due to the fact that rheumatic fever in general appears to be a milder disease—probably because we are now able to protect patients against recurrent attacks. However, optimistic belief that rheumatic fever is in its terminal stages is not justified. This is borne out by the recent survey made by our State Department of Health in co-operation with the Minnesota State Medical Association and the Minnesota Heart Association. This survey was first made in 1955 and repeated in 1958. Many of you participated in it and many of you are familiar with its results.

Minnesota Medical Foundation Lecture presented at the annual meeting of the Minnesota State Medical Association on May 26, 1959.

From this survey, it is conservatively estimated that the physicians of Minnesota are seeing about 3,000 new attacks of acute rheumatic fever each year.[1] This amounts to about one case of acute rheumatic fever in every thousand individuals each year. Although we have no comparable figures for ten or twenty years ago, rheumatic fever can hardly be called a dying disease.

Next, I should like to examine some of the reasons why streptococcal infection, acute rheumatic fever, and acute nephritis, continue to be problems with which we are faced. In searching for answers to this question, we shall examine some of the peculiar biologic properties of the streptococcus, its rather unique chemical makeup, the features which determine its ability to spread from one individual to another, and the extreme variability in clinical response to streptococcal infection which results in no apparent disease in some individuals, mild respiratory symptoms in others, frank tonsillitis in some, scarlet fever in relatively few instances, and occasionally serious late complications such as acute rheumatic fever and acute nephritis. Since we are in the age of widespread use of antibiotics, all of this must be considered in the light of how the streptococcus reacts to penicillin and other antibiotics.

Complexity of Streptococci

Bacteriologists who have attempted to dissect the streptococcus have found it to be a much more intricate organism than the simple chain of cocci which appear on the gram stain. In spite of their small size, these bacteria are complex in biochemical structure.[2] Not too many years ago, we thought of streptococci as producing one toxin, the erythrogenic toxin of scarlet fever. Now we know that hemolytic streptococci produce a large group (at least twenty-three) well-defined biologically-active substances. Many of these substances are both antigenic and sensitizing, resulting in the production of specific antibody and hypersensitivity responses. Many of them are specific enzymes which break down various chemical substances in their environment. To mention but a few of the products of this "enzyme factory," the streptococcus produces two different products which hemolyze red cells, another product which degrades a component of synovial fluid and connective tissues (hyaluronic acid), another enzyme which digests protein, another enzyme which activates a proteolytic system of normal human serum, and three enzymes which destroy DNA (desoxyribonucleic acid), the genetic substance of chromosomes. Except for the erythrogenic toxin (which is apparently the cause of the rash in scarlet fever), we know virtually nothing about how these streptococcal products relate to the signs and symptoms of the clinical disease and its complications.

The streptococci which result in infection of the upper respiratory tract in man are called hemolytic or *beta*-hemolytic streptococci. They produce a clear zone of hemolysis on blood agar plates and must be carefully differentiated from the normal streptococcal inhabitants of the upper respiratory tract which produce an *alpha* or green zone around the colony. Most of the hemolytic streptococci which infect man and all of those which result in complications such as acute rheumatic fever and acute nephritis are members of a single serological group. They are called group A streptococci.

However, this single group of streptococci infecting man, the group A streptococci, is composed of a large number of different types. The existence of a large number of serological types of streptococci is of practical importance, because immunity to streptococcal infection is type-specific. Infection with one type of streptococcus results in immunity to that type but does not result in immunity to the forty-odd other types. This explains why it is possible for a person to have many streptococcal infections during a lifetime. It also accounts, in part, for some of the difficulties in preparing a vaccine against streptococcal infections. With polio, we are dealing with only three types, but with group A streptococci we are dealing with more than forty different types and a complete vaccine would have to contain antigen for each of them.

Spread of Streptococcal Infections

On the average, a person has about one streptococcal infection every five years. Like many other diseases of the upper respiratory tract, streptococcal infections are most common in the school-age child. Young infants are infrequently infected, and when infected, may have a prolonged febrile illness with generalized adenopathy which is quite different from the typical picture of exudative tonsillitis and pharyngitis in the older child and adult. The normal habitat of the streptococcus is the upper respiratory tract in man. It does not parasitize other animals with the exception of primates in captivity. During the course of infection, the bacteria are found in the inflamed tissues of the

pharynx and can be cultured from the nose in about one-third of the cases. Patients who have positive nose cultures are particularly likely to result in the spread of the organism to susceptible individuals. The nasal carrier state does not ordinarily extend beyond two weeks after infection except in patients who have chronic sinusitis. After two weeks the organism may persist for long periods of time in the pharynx or tonsils, but they do not multiply rapidly and the numbers are small. Spread to another person infrequently occurs after two weeks. Persons with streptococcal infections, particularly those who harbor streptococci in the nose, will heavily contaminate the environment about them, including their skin, their clothing and bed clothing, and the air and dust of the room. These streptococci in the environment may live for long periods of time, and it would appear at first sight that this might be one reason for the ability of streptococci to survive and to spread to other individuals. However, these streptococci in the contaminated environment, although still living, are apparently not infectious. Individuals exposed to such environments do not show increased risk of infection. Moreover, when large numbers of streptococci collected from contaminated environments are inoculated into the naso-pharynx of susceptible volunteers, no infection is produced. Some factor other than the ability to survive in the environment must be responsible for the ability of this organism to spread and cause infection in man.[3]

Incidence of Complications

Although many patients with acute rheumatic fever give no clinical history compatible with a preceding streptococcal infection, the evidence is now convincing that all cases of acute rheumatic fever are preceded by a streptococcal infection. About half of these streptococcal infections are subclinical and are neither recognized by the patient nor brought to the attention of the physician. But, in these subclinical infections there is definite evidence of a preceding streptococcal infection on the basis of isolation of the infecting organism or on the basis of an antibody response to streptococcal products. When rheumatic fever follows streptococcal infection, it usually follows after a latent period of about one to four weeks with an average of eighteen days. Obviously not every patient who gets a streptococcal infection develops rheumatic fever. In certain epidemic situations it has been shown that about 3 per cent of patients who experience an untreated streptococcal infection subsequently develop rheumatic fever. Whether the patient develops rheumatic fever or not does not seem to depend upon any factor which can be related to the infecting organism, that is, it is not related to strain variation of the infecting streptococcus, the nature or the severity of the preceding infection, the season of the year or other factors. The importance of multiple streptococcal infections and of a possible genetic peculiarity in the host reaction to streptococcal infections are uncertain at present. Although in epidemic situations the incidence of acute rheumatic fever following a streptococcal infection appears to be fairly constant, the occurrence of acute glomerulonephritis is much more irregular. Indeed, in many large epidemic situations, this complication is not observed at all. This irregularity in the behavior of acute nephritis can be explained by the observation that, whereas acute rheumatic fever may follow infection with any of the types of group A streptococci, acute nephritis follows infection with only a few types of streptococci.[4] These so-called nephritogenic types include types 12, 4, 25, and a type called Red Lake, because it was first isolated on the Red Lake Indian Reservation in Minnesota in an epidemic described by Dr. Kleinman.[5] This last type has now been given the number 49. Only about 15 per cent of patients infected with a nephritogenic type will develop clinical nephritis, so that here again there must be some other factor in addition to the peculiarity of the type of streptococcus which determines whether a patient develops acute nephritis or not.

Frequency of Inapparent Infections

One of the most important factors in the ability of the group A streptococcus to survive in this antibiotic age is undoubtedly the fact that it has tended to go underground. Although scarlet fever still exists, and the disease has been rather widespread in Minnesota and other parts of the country during the past year, it is a relatively mild disease, compared with the severe, prostrating illness which occurred some years ago. Most clinically-recognizable streptococcal infection nowadays presents as a pharyngitis or tonsillitis, but it is important to keep in mind that at least half of the streptococcal infections which occur are either so asymptomatic or atypical that they escape detection. It is, therefore, impossible to recognize and to treat all strep-

tococcal infections. This means that there is a continuing reservoir of untreated infections which can result in rheumatic fever, in acute nephritis, and in further spread of infection. We know that proper treatment of streptococcal infections will prevent rheumatic fever and will greatly reduce the incidence of acute nephritis but it is impossible to eliminate these complications by a direct therapeutic approach because about half of the infections that occur are completely undetected.

Difficulties in Diagnosis of Streptococcal Infections

A second reason for continuation of the streptococcal problem is that even when symptoms and signs are present, streptococcal infections are not easy to diagnose with accuracy.[6] When we think about diagnostic problems among our patients, we do not ordinarily think about patients with upper respiratory disease, yet the differential diagnosis of the etiology of respiratory illnesses is a difficult problem. If the patient has the rash of scarlet fever, we can feel fairly certain on clinical grounds alone that the infection is due to a group A streptococcus. In all other patients, and this includes most of the patients we see nowadays, even the most experienced clinicians cannot distinguish with certainty those infections which are streptococcal in origin and those which are viral in origin. About half of the cases of tonsillitis and pharyngitis in children are due to infections with adenoviruses. These viral infections are often clinically indistinguishable from streptococcal infection. For this reason it is highly desirable to confirm the clinical impression by taking a throat culture, which is examined for the presence of hemolytic streptococci.[7] Throat cultures are relatively easy to do, remarkably inexpensive, and the results are available within eighteen hours. Since early treatment of the preceding streptococcal infection is not essential for the prevention of rheumatic fever, we can feel safe in waiting twenty-four hours or even forty-eight hours for the result of a throat culture before starting treatment in doubtful patients. Treatment can be discontinued in those patients whose culture proves to be negative for hemolytic streptococci. Discontinuance of needless therapy in such patients results in a saving far greater than the cost of the throat culture. As with all laboratory procedures, some care must be given to the technique (including the type of blood used in identifying streptococci), in order not to be misled by the results of the laboratory report. When properly done, throat cultures are extremely helpful in the differential diagnosis of infection of the upper respiratory tract.

Inadequacy of the Usual Penicilin Treatment of Streptococcal Infections

Another important reason for the continuing problem, in spite of antibiotics, concerns the nature of the reaction of group A streptococci to antibiotic therapy. In this, our thinking has been unduly influenced by laboratory reports of the sensitivity of these organisms to antibiotics, These laboratory studies have shown that all group A streptococci are highly sensitive to penicillin. We have carried this test-tube reasoning over to the patient, assuming that it should therefore be easy to eradicate streptococci from the upper respiratory tract of patients. This has not proved to be the case. When penicillin is given over a short period of time the patient feels better, and the number of streptococci in the throat is reduced, but not all streptococci are killed. This finding is of great clinical importance because it has been shown that unless all streptococci are eradicated, antibiotic treatment fails to prevent rheumatic fever. Blood levels of penicillin must be present for ten days in order to kill all group A streptococci and, even then, about 10 per cent of patients may still harbor the infectious organism in the throat. It is extremely difficult to get patients to take antibiotics beyond a period of two or three days when they are having symptoms. But this is essential for maximal protection. The physician can overcome this difficulty by giving a single injection of benzathine penicillin ("Bicillin"), the long-acting depot penicillin which assures prolonged treatment without depending upon the patient to take oral medication for ten days.

Importance of Continuous Prophylaxis in Rheumatic Subjects

Our most solid accomplishment in attempts to control rheumatic fever and rheumatic heart disease has been made in those patients who have already suffered one attack of the disease. In these established rheumatics, it is possible to afford them virtually complete protection against the ravages of repeated attacks of rheumatic fever by placing them on continuous penicillin or sulfadiazine prophylaxis.[8] It is of interest here and of clinical importance that sulfadiazine is quite ef-

fective in preventing rheumatic recurrences when given continuously to rheumatic subjects, but it is ineffective in preventing rheumatic fever when used to treat established streptococcal infections. Like short-term penicillin therapy, sulfadiazine is bacteriostatic. That is, it suppresses growth but does not eradicate the streptococci.

The prophylaxis must be continuous but may be given in any of several ways: Monthly injections of the long-acting Bicillin, daily or preferably twice-daily oral penicillin, or daily sulfadiazine. Again, the intramuscular injection has the advantage of assuring that the patient does not neglect his medication. With our present knowledge there seems to be little reason for the continuing high rate of recurrence of rheumatic fever. This rate was surprisingly high in the Minnesota survey. Forty-two per cent of the patients with attacks of rheumatic fever were recurrent attacks.[9] From this, we can estimate that Minnesota physicians see over one thousand recurrences of rheumatic fever each year. Had these patients been on prophylaxis, it seems likely that most if not all of the recurrences could have been prevented. This alarming percentage of recurrences has stirred interest in the development of a state-wide rheumatic fever prophylaxis program for Minnesota. Such a program is currently being planned by the Minnesota State Medical Association in conjunction with the Rheumatic Fever Committee of the Minnesota Heart Association and the State Board of Health.

Rheumatic subjects must be kept on *continuous* prophylaxis. One cannot rely on treatment of streptococcal infections to prevent recurrences because about half of the streptococcal infections will be subclinical and will not receive treatment. Continuous prophylaxis should be given year-round, and for maximal protection, should be continued indefinitely. Although the incidence of recurrences decreases with age, recurrent attacks do occur in older age groups.

Conclusions

From this brief review, we have seen that streptococcal infections and their complications continue to be important clinical problems even in this antibiotic era. I do not wish to belittle the contributions which penicillin and the sulfonamides have made to the control of streptococcal infections and their complications. These have proved to be highly effective in halting epidemics and in preventing recurrences in rheumatic subjects. And, judging from the number of rheumatic recurrences which develop each year in Minnesota, we still have quite a way to go before we can say that we have taken full advantage of the potentialities of drug prophylaxis.

But antibiotics can never be the final answer to the streptococcal and rheumatic fever problem. In spite of its exquisite sensitivity to penicillin, the group A streptococcus has not been obliterated. It commonly causes infections which go unrecognized because they are subclinical or atypical. It often defies eradication because, in treating infections, antibiotics are not administered for a long enough period of time. Moreover, the mechanisms by which this organism produces acute nephritis and acute rheumatic fever have not been identified, and the complexity of the organism has posed serious practical problems to those who have attempted to devise a vaccine.

Nothing is quite so humbling to the practicing physician and to the investigator as to be continually outwitted by this little bit of an organism which is so exquisitely sensitive to penicillin!

The Role of Voluntary Health Associations In Meeting Future Health Needs

HON. ARTHUR S. FLEMMING
Washington, D. C.

Mr. Flemming is Secretary, U.S. Department of Health, Education and Welfare.

Address presented at annual luncheon, Council on Community Service and Education, Philadelphia, October 24, 1959.

IT MEANS a great deal to me to have the opportunity of participating in this way in the annual meeting of the American Heart Association. Surely, this is one of our nation's great voluntary health agencies. There is no question in my mind at all but that you have made an outstanding contribution in helping our nation to deal in a positive manner with one of our major health problems.

First, speaking in behalf of the United States Government, I want to express to you our deep gratitude for the spirit of co-operation that has characterized all of your relations with the United States Public Health Service. I know of no finer demonstration of an effective pooling of resources on the part of public and private agencies. I am particularly happy to have the opportunity to respond to the suggestion of your program chairman that I address myself to the subject of "The Role of Voluntary Health Associations in Meeting Future Health Needs."

In my judgment, the voluntary health agencies of our nation are representative of America at its best. The agencies have come into existence because of a recognition of a need on the part of the citizens of this nation and they have moved forward with their programs because of a willingness on the part of citizens to make sacrifices in order to meet these needs. That is why I believe they represent America at its best.

I have a great admiration for the work of all of these agencies. This afternoon, however, I want to confine my comment to the role of the American Heart Association in carrying forward research, education, and community services in the field of heart disease. In doing so, I will give expression to certain hopes that I have as I think in terms of the future of your Association.

First of all, I hope that you will continue to place major emphasis on research activities.

As we all know, our nation in the past few years has increased its investment in the field of medical research at a very rapid rate. Not only has there been a sharp increase in government appropriations for this purpose but there has also been a marked increase in the amount of the funds made available for this purpose from private sources.

As many of you here know, a distinguished group of experts under the chairmanship of Dr. Stanhope Bayne-Jones recommended a little over a year ago that this country should think in terms of reaching the point where it would be investing annually a billion dollars in medical research. They also suggested that 50 per cent of these funds should come from the Federal Government and the other 50 per cent from state and local governments and private groups. Now, as you undoubtedly also appreciate, at the present time we are just slightly past the half-way mark toward this goal. It is estimated that during the year 1959 about $575 millions will be spent for medical research, on the part of government at all levels and on

the part of private groups. Furthermore, the Federal Government is assuming responsibility for about one-half of this total investment.

I believe that the goal that was suggested by Dr. Bayne-Jones and his associates is a reasonable goal. I am even more convinced that their recommendation for dividing the responsibility on a 50-50 basis between the Federal Government on the one hand and governments at other levels and private groups on the other hand is absolutely sound. I believe that if the Federal Government should assume a larger share of the total responsibility it would in the long run operate against our achieving optimum results in the medical research field.

Now, it seems to me that it is clear that if we are going to divide the responsibility for the support of medical research on a 50-50 basis, our support of medical research from private sources must move ahead at an accelerated pace. This, it seems to me, is the answer that should be given to those who ask the question: "In view of the fact that the Federal Government is spending such large sums in medical research, is it necessary for me to continue to contribute to private organizations that use a portion of their funds for the same purpose?" I feel that it is not only desirable for the citizens of our nation to continue to make contributions to private health agencies for research, but that it is imperative for them to increase their contributions if we are to keep our over-all medical research program on a solid foundation.

I think it would be a sad day for medical research, if, for example, we should ever reach the point where the Federal Government was putting up 80 to 90 per cent of the total investment in all research. We must, if at all possible, hold to this concept of a 50-50 distribution of responsibility.

In the second place, I hope that the American Heart Association will continue to place major emphasis on its program of education. I think it is absolutely impossible for anyone to really describe in an effective manner the impact of your educational program on our nation. It is certainly clear, however, that both professional and lay personnel have a far better understanding of the nature of this disease and of the steps that can be taken both to prevent it and to rehabilitate those who are its victims as a result of your program. Activities in this area, it seems to me, have complemented in a very meaningful manner the activities of public health agencies but they have been of such a nature that if you had not done what you have done, the public agencies by their very nature would have found it impossible to step in and carry forward the kind of program that you have carried forward so effectively.

I am particularly interested in the contributions that you have made in the education of professional personnel. I think that one of our most challenging opportunities in the health field is to develop educational programs that will insure the fact that our citizens will reap the benefits of research programs. The breakthroughs that take place as a result of medical research will be of little benefit unless we can devise ways and means of applying the results of the breakthroughs to the general practice of medicine. Surely you have rendered an outstanding service in this area. I hope that your activity along this line will be stepped up in the years that lie ahead.

I am confident that as time goes on the Federal Government can and will be of great help to you in the furtherance of your educational activities.

The Public Health Service's National Health Survey, for example, will soon publish its first figures on heart disease and high blood pressure. These data will come from the household interviews which constitute one major part of the health survey program. From them we can learn about medical care, about the extent to which people's usual activities are interfered with—whether they lose time from work, whether they take to their beds, and so forth.

I am told by the Public Health Service that the forthcoming report will show that an estimated 4,849,000 of the civilian non-institutional population, or 28.3 persons per thousand, believe they have heart disease. High blood pressure without a heart condition is reported for another 5,268,000 people or 31.3 persons per one thousand. About 98 per cent of these reported conditions have received medical care. The amount of disability caused by heart conditions is far greater than that resulting from high blood pressure alone. The average person with a heart condition has to restrict his normal activities for forty-nine days during the year. On the average, eighteen of these

days are spent in bed. However, the average person with high blood pressure restricts his activities for only nineteen days, including six days spent in bed.

It is clear, however, that this information, interesting and important as it is, provides only a part of the picture—the part that persons in a household can give to an interviewer. In order to round out the picture, a health examination is needed—one that will produce prevalence data and will supply, in medically acceptable terms, precise diagnosis and physiologic measurements such as blood pressure levels. Such an examination has been worked out by those who have responsibility for the National Health Survey and has been field tested, up to the present time, in three pilot projects. It is now entering gradually into the production stage. A group of these examinations is scheduled for this area, the Philadelphia area, beginning on October 29.

I am sure that as information of this kind is made available to you, that it will be possible for you to use it effectively in your own educational program. And as I think in terms of your educational program, there is one other point I would like to make. There is no question in my mind but that the educational programs of this Association and other similar associations have played a major part in developing support for governmental activities designed to deal with these major health problems. This is a point which it seems to me should never be overlooked. So for all of these reasons, I hope that you will not only continue, but that you will step up, your program in the educational area.

In the third place, I hope that community service will continue to be one of the outstanding characteristics of the work of this Association. I recognize, of course, that this activity is closely related to your educational program.

I am personally in complete agreement with the concept that the voluntary health agency, with its unique ability to involve and utilize volunteers from all levels and professions of the community, is in a very strategic position to initiate and to carry forward a type of community service that would otherwise not exist. In this connection, in order to be a little more specific, I am a great believer, for example, in the kind of service that an association of this kind at the local level can render in the whole field of rehabilitation. And the better acquainted I become with the welfare field as a whole, the more convinced I am that as a nation we must make an increasingly large investment in rehabilitation activities. The time has come for us to put more emphasis than we have on preventing some of the situations that have cost us a tremendous amount of money. That is why, for example, I am very excited over the possibilities that are inherent in our Federal-State program of vocational rehabilitation. Not only does that provide exciting possibilities, but it seems to me that the opportunities that confront an association such as this in the rehabilitation area are likewise very exciting opportunities, and I am glad to note the increasing emphasis that you are placing on this type of community service.

I personally do not agree with those who feel that the voluntary health agency should step out of the community service field and leave that field to other agencies. I recognize that these other agencies can and will continue to render a very significant service, but I believe it is a question of "both-and" and not "either-or."

Furthermore, I believe that as a society, we are capable of providing the kind of support that will make it possible for the voluntary health agencies and other agencies in the community to carry on this kind of service. After all of the agencies have done their best within the community, there will still be a great deal that remains to be done.

In my judgment, as I think in terms of your total activity—those of research, education, and community service—and as I think in terms of comparable activities on the part of other associations, our nation should not only continue to provide the support it is now providing for voluntary health agencies, but should substantially increase this support.

Now, I am not going to discuss here this afternoon the best method to follow in order to maintain and increase the support you are receiving. I recognize that this is a highly controversial area, and I recognize that there are various schools of thought when it comes to determining what methods should be followed. I'd just like to say this by way of a generalization: I am out of sympathy with the idea that in this nation we should make giving as painless as possible. If the day ever comes when we hesitate to place before our fellow citizens the needs of their fellow human beings and challenge them to make sacrifices in

order to meet those needs, that will be a sad day for our nation.

May I state just this one other suggestion or express this one other hope: I hope that if, and I believe this will take place, there is increasing support for your activity that you will not only think in terms of the service that you can render in our own nation, but that you will also think in terms of the increasing service that you can render in the field of international health. Over a period of the last sixteen months I have become increasingly impressed with the fact that our nation has an unparalleled opportunity to convey to the peoples of other nations our concern for their welfare by making increasing contributions to the strengthening of international health activity. There is a role here for the government, but there is also a role for the voluntary agencies that the government can't possibly fill. I believe that it is possible for us to carry forward as a nation a truly effective crusade for peace by helping to meet the health needs of other people, and I certainly hope that this association will continue to play an active part in the plans for the development of this crusade.

Then, may I sum up all I have been trying to say in this way: I am convinced that in carrying forward your activities you are not only helping to improve the health of the people of this nation and of other nations, but you are also helping to strengthen our spiritual foundations. You are engaged in this activity because of a conviction on your part that you have a spiritual obligation to love your neighbor or help your neighbor realize his highest potential; and your fellow citizens, as they come in contact with your work in this particular area, become aware of the fact that you recognize this spiritual obligation. I believe that as we carry on activities of this kind among the other peoples in the world they, likewise, will recognize that we recognize a spiritual obligation. The more we recognize this spiritual obligation, the more we do in the direction of putting into motion those spiritual forces that alone will provide us with a spiritual breakthrough that will ultimately lead us into a pathway of peace.

So, this afternoon, I personally would like to express my deep appreciation for the major contribution that you are making, and I know will continue to make to improve the health of the citizens of our nation and of the other nations of the world, but above all, I want to express my own appreciation for the major contribution that you are making in strengthening the spiritual foundation on which our nation rests.

THE MEASUREMENT OF SPASTICITY

EDITORS WANTED FOR MINNESOTA MEDICINE

This editorial is written with the thought that it may serve to locate the best available physicians for a most important project for the advancement of medical communication and science in Minnesota.

A reorganization of the method of publication of our journal is in process. The Board of Editors is seeking a number of physicians who have a desire to contribute to this enterprise. Experience in any phase of journalism, business, or related fields would be an asset. A determination to become proficient in some aspect of journalism such as the psychology of visual communications, printing, procurement of manuscripts, editing, finances, advertising, public relations, art, combined with a whole-hearted desire to contribute two or more hours a week to this effort could be most important.

If you are personally interested or know of some physician who fits the need, please contact the editor-in-chief immediately.

REHABILITATION IN MINNESOTA MOVES AHEAD

Rehabilitation has been defined as the physical, mental, social and vocational restoration of handicapped persons to the fullest usefulness of which they are capable. Adequate total rehabilitation of the handicapped citizens of Minnesota requires community effort in which physicians and ancillary workers in the health field combine with educators, educational psychologists and vocational counselors, and with men and women of good will in the community at large in developing adequate services for medical, psychologic, social and vocational guidance that will assist each handicapped person to help himself to achieve physical and vocational independence.

The Minnesota State Board of Health has developed a plan for the organization of five general rehabilitation centers in key medical institutions in the state. Three of these centers for the total rehabilitation of the handicapped already have been established, including (1) the Department of Physical Medicine and Rehabilitation in the Mayo Memorial Building at the University of Minnesota Hospital, (2) the Section of Physical Medicine and Rehabilitation at the Mayo Clinic and (3) the combined project of the Kenny Institute, Curative Workshop, and Minneapolis Rehabilitation Center group in Minneapolis. It is proposed, eventually, to establish a key center in Duluth and, finally, a center in St. Paul.

Likewise, the Board of Health has developed a rather unique program for establishing smaller satellite centers for provision of rehabilitation services in various rural communities.

Under a grant from the Federal Office of Vocational Rehabilitation, the Office of Vocational Rehabilitation in the Department of Education and the State Services for the Blind in the Department of Public Welfare are conducting a complete survey of the rehabilitation resources of the state. A complete description of these rehabilitation facilities soon will be published and distributed to all practicing physicians within the state. The State Division of Vocational Rehabilitation has undergone extensive reorganization in the past four years and, under the leadership of August W. Gehrke, Assistant Commissioner for Rehabilitation and Special Education, the facilities for vocational rehabilitation of handicapped Minnesotans has expanded to a point at which the number of persons vocationally rehabilitated has more than doubled. In 1955, a total of 582 handicapped citizens of Minnesota were rehabilitated, while during the fiscal year 1958-1959, a total of 1,173 handicapped Minnesotans were returned to new occupations through the work of the Division of Vocational Rehabilitation of the Department of Education.

A Medical Advisory Committee to the State Division of Vocational Rehabilitation (under the chairmanship of Dr. Corrin H. Hodgson, of Rochester, and the vice-chairmanship of Dr. William J. Lick, of St. Paul, who is State Medical Consultant to the Division of Vocational Rehabilitation) is accomplishing a great deal in familiarizing the physicians of this state with the importance of this joint community humanitarian effort. This committee serves also as the Com-

mittee on Rehabilitation for the Minnesota State Medical Association and is working closely with the parent Committee on Rehabilitation of the American Medical Association.

It is evident that real progress is being made in the providing of co-ordinated services for the increasing numbers of handicapped persons in Minnesota, but it is also evident that much more needs to be done in order to meet this enormous medical and social problem, in which every physician of Minnesota should be deeply interested.

In subsequent editorials, additional information concerning this magnificent effort to help the handicapped help themselves will be described. The support and understanding of all Minnesota physicians are earnestly solicited.

FRANK H. KRUSEN, M.D.

RADIATION TREATMENT OF CANCER OF THE LUNG

Surgery and radiation are the two chief methods available for the treatment of carcinoma of the lung. The first choice always lies in surgical removal if this is at all possible. Often surgery is justified not only to definitely establish the diagnosis but also to see if a reasonable chance for complete removal is possible. If, during the exploration, the lesion is found inoperable or nonresectable or if only a partial resection is done, then radiation may be indicated as a direct postoperative procedure to attempt palliation for a lesion that in a rather short time is almost certain to cause considerable morbidity. Radiation is also indicated in cases where a definite diagnosis of inoperable lung cancer has been made in some other way than by exploratory thoracotomy. There is no place for radiation treatment for carcinoma of the lung that can be removed surgically unless the patient refuses surgery or some definite surgical contraindication exists.

The results from radiation treatment of lung cancer are most discouraging, regardless of the type of radiation source (high voltage and supervoltage x-rays or cobalt radiation) or the manner in which these modalities are used. This, however, should not deter us from using this method for its palliation effect, which in many ways can be of very great comfort to a patient suffering extensively from such symptoms as bronchial obstruction, hemorrhage, intractable cough or pain. Used judiciously, the palliation can be very marked at a level well below the stage where radiation morbidity can offset its value.

Regardless of the cell type of the lesion, the records show only a very few cases where a radiation cure of a carcinoma of the lung seems proved. The more anaplastic types, such as the oat-cell and the small cell carcinomas may show a rapid early response to radiation but their quick dissemination makes it impossible to stop their inevitable advance. The epidermoid and the adenocarcinomas are quite resistive and show a rather poor response to radiation and, therefore, higher tumor dosage is necessary but usually not sufficient to arrest their extension except temporarily. However, in spite of this poor response to radiation for the possibility of a cure it is possible to make the patient much more comfortable by giving him relief from distressing symptoms. In some cases, this is done by treating, in a sense, prophylactically before these symptoms arise and to postpone their occurrence. Radiation may be withheld, especially where there has been surgical resection of some degree, until such a time as when pain or hemorrhage demand it or when breathing is showing some interference from obstruction and atelectasis. Each case needs individual evaluation and as far as possible a plan of treatment should be set up in a way that will give the greatest degree of palliation.

The indications for radiation treatment of carcinoma of the lung may be instances where tumors are operable except for their very high grade of malignancy, or where the age of the patient or some other surgical contraindication exists, and in tumors that are too close to the carina to permit excision. It is indicated in the frankly inoperable lesions where some degree of palliation can be offered. Contra-indications for radiation therapy might be a poor general condition of the patient, including fever, high pulse rate or other signs of infection or shock. Radiation to infected areas of the lung may cause rapid necrosis which can frequently be accompanied by severe and possibly fatal hemorrhage. It is usually unwise to treat through an area of tuberculosis, although at times this can be done deliberately as a calculated risk. If the tumor involves a large portion of the lung or if visceral metastases are present, radiation is not indicated. Extensive pleural effusion diffuses the radiation effect to

such a degree that proper dosage cannot be built up in the tumor area.

Palliation treatment, therefore, is the chief and almost the only reason for radiation therapy for primary carcinoma of the lung. This can be directed to the relief of pressure on large vessels and particularly the superior vena cava. Bronchial obstruction and dyspnea can be relieved by its effect on enlarged mediastinal nodes. Frequently hemorrhage of varying degrees can be temporarily stopped. Intractable cough or pain often can be markedly diminished or stopped if the lesion shows any appreciable degree of radiation sensitivity.

In planning the radiation treatment for the patient with primary carcinoma of the lung, it is necessary to keep in mind that only in the most favorable set of circumstances can one even entertain the remote possibility of a cure. Palliation treatment, however, should not be only a casual attempt, but one carefully directed to give the greatest possible degree of help with radiation morbidity kept at an acceptable level. Nothing is gained by substituting radiation complications that may be as bad or possibly worse than the disease being treated. The types of radiation used seem to have relatively little variation in the end results achieved. High voltage radiation in the range of 250 to 400 thousand volts, the supervoltage in the range of 2 million or more volts and cobalt therapy are all useful. Each may have some advantage over the others but with none is the result a satisfactory one. There is no appreciable help to be expected from nitrogen mustard and allied substances in the treatment schedule for carcinoma of the lung.

Although radiation therapy takes second place to surgery in the treatment of carcinoma of the lung in the operable, asymptomatic cases, it can join with surgery greatly improving the lot of the patient that has only a partially resectable lesion. It can take over entirely where surgery has nothing to offer by helping to alleviate the many types of suffering such patients often must undergo. Until more effective treatment methods can be found, the best improvement in results in the treatment of primary carcinoma of the lung will come from finding a greater number of localized asymptomatic lesions.

J. Richards Aurelius, M.D.

PRESCRIPTION: RECREATION

Medicine is performing miracles to extend life, and it is clear that ways must be found to make the added years not just endurable, but enjoyable and useful.

Of all the problems identified with aging, the one most common to the greatest number of senior citizens is what to do with the added leisure of retirement years. Regardless of income, the man or woman whose life has been full of the demands of a job and growing family finds that time, which should be a boon, is too often a burden. Many are wasting as much as a third of a lifetime in a "rocking chair existence."

Our changing society, with its small homes, transient and scattered families, enforced retirement and automation, provides few opportunities for the useful employment of time that the elderly enjoyed thirty years ago, and retirement often marks the beginning of a gradual withdrawal from all outside contacts.

Physicians are aware that they are sometimes called, not because an older person is actually ill, but because he has a desperate need to talk to someone, and that the serious medical and mental conditions of some are often the result of nothing more than the heartaches of loneliness and the frustration of too many empty hours.

Dr. Paul Dudley White warns that "Physical and mental inactivity, not senility, are responsible for many of the ailments of old age," and Senator Thomas C. Desmond, former chairman of the New York State Joint Legislative Committee on Problems of Aging, writes: "Pessimism probably kills more old folks than disease. I suspect that often heart trouble is caused by losing heart. Our elderly are not often vanquished; they are more likely to surrender. They are less likely to give out, than to give up."

For many people, the end of existence is almost worse than not existing at all. Forty per cent of the patients in our mental hospitals are sixty-five or over, and we have not begun to meet the need for other types of institutional care for older people. Prevention is far lass costly.

A number of studies conducted in the past few years point to recreation and social programs as one means of effective prevention. In Hennepin County, not one member of the more than fifty Golden Age Clubs has been admitted to a mental hospital. At the William Hodson Center in New York, a controlled study showed clinic attendance

reduced by 37.8 per cent in less than a year from the time members became active. Members of social and recreation groups frequently report that their physicians have been surprised at their improvement and have reduced or discontinued medication after they found companionship and new interests in activity programs.

Fortunately, the need for this type of program is readily recognized, and many communities have organized groups. Through sponsorship of these programs by recreation or social agencies, churches, civic, fraternal, educational or social organizations or independent committees, an awareness of other problems grows out of this more intimate association with older people.

Until the late forties, it had not occurred to anyone that older people might enjoy meeting together as other age groups do for companionship and fun, even though for many years programs were planned around the common interests and abilities of other age groupings, such as children seven to nine, nine to twelve, teenagers, young adults, and so on. While response to the first groups organized was far beyond expectations, and Golden Age Clubs mushroomed all over the country, some older people still resist the comparatively new concept of recreation as a necessary part of healthful living, and require a considerable amount of stimulation before they will participate.

Dr. Paul Haun, Director of Professional Education, Eastern Pennsylvania Psychiatric Institute, pinpointed one of the reasons in an address before the eleventh annual conference of the Pennsylvania Recreation Society when he said, "We have inherited a set of unspoken attitudes which have been superimposed on these simple and correct distinctions between work and play. Sin, somehow or other, became an issue. Work was virtuous rather than only proper and desirable. Play was shameful, rather than necessary and pleasant. All forms of amusement wasted time and were clearly immoral, partly because they diverted man's energies from work, but more significantly because they were enjoyable, and pleasure itself was a mortal sin." We are learning that for some, only work or a work substitute will ever be an acceptable form of recreation.

It must be remembered that this generation has known little, if any, leisure, and comparatively few group experiences; that older people are often influenced by false concepts of age, especially since they remember that their own parents were "old" at a much younger age; that their opportunities to participate in more than a few types of recreation have been limited.

We must also remember that even though aging is a "slowing down process," and we become a little impatient with the shell in which we live as we grow older, the spirit is often as young as it ever was, and as venturesome. The needs are the same as those of any other age group—the need for social relationships with other people, the need to be useful, the need to create something or to contribute something, the need to learn, the need to forget oneself in relaxing occupations, the need for recognition.

A good recreation program should meet all of these needs by offering a wide choice of activities which are stimulating both mentally and physically, including many this generation has "never had time to try," and would not ever think of trying in competition with younger people.

The interests of older adults are as broad and varied as those of any age group, and we have long since abandoned the idea that "you can't teach an old dog new tricks." Lively discussion follows lectures on physical and mental health, nutrition, family problems and other subjects of special interest to people of this age. Unexpected and neglected talents thrive under the stimulation of classes in creative crafts. Dancing, active games and mild physical exercise stimulate good circulation and appetite, a sense of well-being and a brighter outlook, and moreover are fun. Community singing, talent shows, orchestras, mental games, book reviews, movies, travelogues, fashion shows and birthday parties challenge the interest of those who in the beginning may refuse to participate in anything but card games, simply because card playing is the only kind of recreation they have known.

Volunteer service projects provide an opportunity to be useful, and at the same time utilize the experience and know-how of senior citizens to the advantage of the whole community. Among the many types of useful services needed are "friendly visitors" to the handicapped and housebound of their own age group who are unable to leave their four walls and have lost touch with the community.

Participation in recreation programs of this kind, the constructive use of leisure time, will

benefit many who are now hesitant about joining one of these groups—if the physician prescribes for healthful, more enjoyable living.

(Mrs. A. W.) Opal Tews, *Supervisor, Senior Citizens Leisure Time Activities, St. Paul Bureau of Parks and Recreation*

URINARY DIVERSION

Surgeons have searched for nearly a hundred years for a safe method of diverting the urine above the bladder. Some types are relatively safe from the viewpoint of surgical mortality, but none is free from the danger of late complications affecting the upper urinary tract. The variety of methods and techniques so far devised attest a fundamental dissatisfaction with results of all varieties of urinary diversion.

The possible indications for diverting the urine, while not very frequent in occurrence, include quite an array of diverse disorders:

1. The bladder has to be removed.
   Primary and secondary neoplasms.
2. The bladder cannot be made to function adequately.
   (a) Neurogenic vesical dysfunction.
      (1) Atonic bladder with large residual urine.
      (2) Incompetent sphincters.
   (b) Irremediable urethral strictures.
   (c) Irreparable vesical fistulae.
   (d) Serious congenital anomalies.
      (1) Exstrophy.
      (2) Complete epispadias.
      (3) Atonic bladder with congenital ureterectasis.
      (4) Obstruction at vesical neck with "paper thin" ureters.
   (e) Inoperable vesical neoplasms (for palliation).
3. To arrest renal damage from unsatisfactory ureterosigmoidostomy.
4. Severely contracted bladder.
   (a) Tuberculous or posttuberculous.
   (b) Interstitial cystitis ("Hunner" ulcer).
   (c) Postinflammatory fibrosis (nonspecific infections).

I should like to emphasize that urinary diversion is to be considered *only* when simpler or safer methods fail or are inapplicable.

An almost embarrassing array of methods is available, all having their own peculiar advantages and disadvantages. Simplest, and safest in terms of surgical mortality, are nephrostomy and ureterostomy. However, they burden the patient with catheters which must be changed and which, serving as foreign bodies, all too often lead to infection, renal lithiasis, and eventual renal failure. Therefore, pending the development of dependable methods not requiring inlying catheters, these operations are usually used only as temporary expedients, or as permanent ones in poor surgical risks with short life expectancies.

Ureterosigmoidostomy is the best method from the patient's viewpoint because it does not require the wearing of catheters or bags. However, it connects the urinary tract, intended to function in a sterile environment, with a heavily infected organ capable of generating pressures higher than those normally found in the urinary tract. All too often this leads to hydronephrosis and pyelonephritis. As these lead to impaired renal function, hyperchloremic acidosis may become a problem.

Many attempts have been made to protect kidneys which have been connected to the colon: diverting abdominal colostomy (Mauclaire); and perineal colostomy (Gersuny) are most logical, but have not been widely used. Both provide a relatively clean urinary reservoir, the latter without the disadvantages of an abdominal stoma.

Because bringing the end of the descending colon through the anal sphincter may imperil its blood supply, abolish the defecation reflex, and render the anal sphincter inoperative by overdistending it, Delev isolated a segment of sigmoid, and made an end to end anastomosis around it. He narrowed its lower end to the diameter of the urethra and brought it out between the anterior rectal wall and the anal sphincter. He closed its upper end and anastomosed the ureters to it. He has reported three successful cases.

Others have sought to prevent contamination of the kidneys by interposing a segment of ileum between ureters and sigmoid. Since ileac peristalsis is relatively feeble, being able to resist back pressures of but 7 to 25 centimeters of water (defecating pressures rise to 280 centimeters of water), this is an idea of doubtful merit.

Gilchrist and Merricks have used the isolated cecum and ascending colon as a urinary reservoir, catheterizing it through a segment of terminal ileum opening to the outside. Repeated catheterization cannot but cause damage to the urinary tract in the long run.

The latest thing (first used by Shoemaker in 1908) is diversion through an isolated segment of ileum with one end closed and the other open-

ing upon the abdomen and fitted with a collecting bag. This has been popularized in this country largely by Bricker. It is alleged that, since the ileum is a conduit rather than a reservoir, absorption of urinary constituents is negligible. This is turning out to be false in patients with seriously impaired renal function; bitter disappointments with use of the ileum in congenital ureterectasis is causing some surgeons to turn back to cutaneous ureterostomy with variations intended (with variable success) to avoid the use of catheters.

C. D. Creevy, M.D.

LAW-MEDICINE PROBLEMS: CONFLICT OR CO-OPERATION

The problems confronting the law-medicine relationship begin long before the courtroom. The adversary proceedings of a common-law trial merely illuminate these problems and ignite the participants—lawyers and doctors.

The first problem is a lack of understanding of the other profession, its purposes and its practices.

Law is man's tool to provide peace and order in a community, human dignity and human rights to each citizen of the community, and equal opportunity for physical, mental and spiritual growth to all citizens. The law replaces violence in the settlement of human conflicts and controversies. Thus the community can be at peace. The law protects individuals with fair hearings, representation by counsel, examination and cross-examination in trials to attempt to acquire truthful facts to which just laws will be applied and fair decisions thereby rendered. Lawyers are the lubricating oils which facilitate the administration of justice. Lawyers deal with a client and the community simultaneously. The client is not isolated from other men. The very fact that he is a client means he is involved legally with another man or the community. The lawyer's practice includes two sides to every legal problem, both human. The adversary procedure of common law has been the best available method to assure that both sides can present their viewpoints in the strongest manner. The decision-maker-judge, jury, referee, board or commission, must then resolve the conflict to maintain peace and order, not necessarily to please one client or the other. The lawyer practicing as a lawyer is not a decision-maker. He is counselor and adversary.

Medicine is man's tool for understanding the human body, for preventing, alleviating and curing human illnesses, diseases and injuries, and for the continuous extension of the human life-span. Medicine provides man with hospitals, clinics, laboratories, and doctors' offices in order to determine truthful medical facts to which the doctor will render an opinion and apply preventive or therapeutic measures. Doctors are lubricating oils too, but they are more. The doctor is also a decision-maker. He prescribes for his patient; the patient abides. His patient is not involved medically with another patient. The doctor need not advocate his patient's case of pneumonia against an adversary patient's pneumonia.

The doctor jousts with a germ; the lawyer with another opposing human being. The doctor's practice does not entail adversary measures against another person; the lawyer's does. Adversary procedures like trials are foreign and distasteful to doctors. His practice precludes their use and his experience denies their wisdom. To the lawyer such procedures are the best means of resolving conflicts between two people when negotiated settlement is impossible. His practice and experience make these procedures natural and acceptable. The doctor views the lawyer as one who often doesn't want medical truth because of his cross examination tactics. The lawyer views the doctor as one who places himself in the position of a god whose ideas are not to be questioned and whose facts are not to be challenged.

Obviously in our complex society today the frictions between our professions are increasing and will continue to do so. The first problem is to understand better the differences between the two professions. Through writings, addresses, joint educational experiences, both lawyers and doctors can be stimulated to appreciate the other's professional goals and practical values to society.

Given this appreciation and the desire to understand the other profession, more subtle law-medicine problems can be investigated.

An immediate challenge appears in the area of communications—the meaning of words like "cause." What "causes" a patient's ill health may be several factors. The doctor does not need to find one direct or proximate cause upon which to diagnose his case. He may even be unable to determine one "cause" in the true sense but experience will enable him to alleviate or cure. "Cause" is important but not crucial to the medical man.

The lawyer finds "cause" to be crucial. In determining whether a defendant be liable in damages to a plaintiff for personal injuries, the decision-maker must determine by the greater weight of the evidence that defendant's misdeed was the probable direct or proximate cause of plaintiff's injury or illness. Plaintiff cannot recover *legally* unless this "cause" is determined. Plaintiff can recover *medically* whether this "cause" is determined or not.

When a doctor becomes a medical expert witness, he must speak words with legal meanings not medical meanings. Even before he becomes a witness, the lawyer must explain to his doctor witness the full significance of the communications confusion.

Other problems of concern to the law-medicine relationship are the best methods for using medicine as a source of truth by which justice can be achieved. Do qualified doctors refuse to provide medical evidence? Do lawyers bar respectable medical witnesses by courtroom histrionics and innuendos? Is the doctor best able to present evidence in the capacity of an adversary witness rather than as a witness for the court subject to cross-examination by both parties? Can the doctor's evidence be in writing and better used in pre-trial conferences where opposing parties have an opportunity to settle the conflict with the judge's guidance? Will mutual exchange of all medical evidence in writing between opposing parties prior to a lawsuit stimulate negotiated settlements conserving the time of lawyers, doctors and courts? These questions demand great thought among the members of both professions. Proper answers will not only benefit the two professions but more important, society as well.

The interdependence of law and medicine is merely one segment of modern man's interdependence with his fellow man. All men yearn for the goals of law—peace and order, human rights, equal opportunities—and of medicine—understanding the body, preventing and curing man's ills, lengthening his life span. May the wisdom of our ancient intellectual disciplines not be fearful of our common problems; rather, let this wisdom be used to solve these problems.

Oliver Schroeder, Jr.

Mr. Schroeder is Professor of Law; Director, The Law-Medicine Center, Western Reserve University, Cleveland 6, Ohio.

PAINLESS HEALTH APPEALS

Can giving to health appeals really be made painless?

You will be interested in what Secretary Arthur S. Flemming of the Department of Health, Education and Welfare said about this, and other questions currently in the news, at the recent annual meeting of the American Heart Association in Philadelphia. The Secretary spoke at a luncheon of the Association's Council on Community Service and Education on the subject, "The Role of Voluntary Health Associations in Meeting Future Health Needs." (See page 44).

USE OF ILEUM IN URINARY DIVERSION

Minnesota Blue Shield

Minnesota Blue Shield this month issued a letter informing participating doctors of medicine throughout the state that it is in the process of centralizing all services within its own organization following action by Blue Cross terminating the working agreement between the two Plans.

At the same time, Blue Shield advertisements in state newspapers advised Blue Shield subscribers that their Blue Shield coverage and benefits were unaffected by the organizational change.

The letter to the doctors from Dr. C. A. McKinlay, president of Minnesota Medical Service, Inc., announced that a Blue Shield division of Enrollment and Service had been established which has assumed responsibility for Blue Shield sales and services. Ben Stephens, Jr., for the past seven years manager of Blue Shield's claims department, was appointed director of the new division.

"Representatives of this Division," the letter continued, "will be loyal members of Blue Shield's immediate family and will concentrate exclusively on sales and service to Blue Shield subscribers and participating doctors of medicine."

Dr. McKinlay also announced Blue Shield's plan for a new and "less expensive" headquarters and that the organization had leased IBM equipment for claims payments, accounting, billing, and record-keeping.

In conclusion, Dr. McKinlay wrote: "Your Minnesota Blue Shield Plan is now free to expand its benefits over the full range of services rightfully within the realm of medical practice. It is a challenge—and an opportunity. With your confidence and support, your Blue Shield Plan can now look forward to the greatest period of achievement and progress in its twelve-year history."

* * *

Richard T. Crist, President of Minnesota Blue Cross announced today that effective immediately the organization will operate independently.

Crist explained that Minnesota Blue Shield, the medical-surgical plan for which Blue Cross had been performing administrative and sales functions since the plan (Blue Shield) was organized in 1947, has expressed a desire to set up their own sales force.

Crist said that Blue Cross has been of the opinion that a single sales force could service both organizations more efficiently and economically . . . "and to the best interest of all Blue Cross and Blue Shield members."

"Though this difference in opinion has led to the setting up of two separate organizations, Blue Cross will continue to handle necessary administrative functions as long as they are vital to providing the best possible service to all members or until such time when Blue Shield is staffed and equipped to operate on its own," Crist said.

Crist pointed out that the announcement will in no way affect present rates or benefits.

* * *

Minnesota Blue Shield now has available an ample supply of the new medical service report forms for distribution to physicians. A new form was developed to facilitate reporting of diagnostic x-rays and diagnostic laboratory services under the diagnostic program recently inaugurated by Blue Shield.

These medical service reports should assist physicians and their office personnel in reporting diagnostic services as well as the other services covered by Blue Shield contracts. If properly completed the claims forms will also facilitate Blue Shield processing, particularly with respect to diagnostic x-rays and diagnostic laboratory services.

The new program permits allowances only for those diagnostic x-rays and diagnostic laboratory services which are necessary to the diagnosis or treatment of a sickness or injury. Therefore, the physical signs or symptoms will often be the basis for Blue Shield payment and, consequently, information regarding the physical signs or symptoms will be as necessary to prompt claims handling as will information regarding the final diagnosis. Adequate information on all medical service reports and particularly those involving diagnostic services will eliminate many inquiries to physicians' offices which are burdensome to doctors, their office personnel, and Blue Shield.

The medical service report includes one other significant change in the form of an addition. This pertains to the new Senior Citizen Plan and involves the net worth factor which partially determines eligibility for unlimited subscriber benefits. The senior citizen subscriber is responsible for furnishing this information and, in fact, for completing the upper portion of the medical service report form if the doctor's office desires. In the case of any patient sixty-five years of age or older who is enrolled under a senior citizen contract, it would be of value in processing such claims if information regarding the income status and the net worth were included upon the report at its original submission.

Clarence Jacobson, M.D.

President, Minnesota State Medical Association

President's Letter

THIS IS MEDICINE—1960

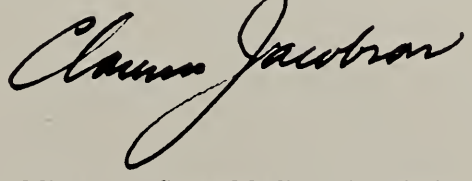
Greetings:

The honor of being chosen to represent you as your President for this year culminates many years of happy associations with the practicing physicians of this state.

A constant desire to improve our standard of practice, to gain the confidence of the public we serve in the cause of rendering the best service to the greatest number, dominates our conferences and medical meetings.

Problems are ever present. The beginning of a New Year gives one hope for better solutions to these perplexing situations which are carried over from the old.

New challenges appear on the socio-economic horizon. Our colleagues in the old world were unable, and probably unwilling, to face the facts of economic change. They chose to remain aloof, and consequently were left without a voice to encourage better medical care when the need became manifest.



Our willingness to seek out our representatives in government, locally, state, and nationwide in an attempt to work out wise legislation is evident. The doctor has, as a result, been permitted to work in a climate of freedom which is essential to better standards of practice.

Responsibilities in a free economy demand self-control and vigilance. Our available voluntary prepaid insurance services are meeting most of the medical needs in our State. Rising costs brought about by inflationary forces are rapidly challenging our voluntary system. To circumvent them, we need to strengthen our voluntary system by avoiding internal dissension and encouraging responsibility through better communication between all our voluntary health insurance agencies. Our strength lies within our county societies who are on the active front. Through their chosen representatives to the state associations, we are demonstrating our willingness to meet and bring to effective solution many of these perplexing problems to the best interest of our patients.

We face a year of changes and possible economic upheavals which we can, and must, face together through our well-informed and well-equipped medical organizations. The Forand Bill continues to be our immediate concern. Members of Congress must be contacted by us and our friends and made to understand that we are aware of the unsound and unfair features of this social legislation. We are also aware that it leads us directly to an all-out nationalized medical program. Through our voluntary insurance agencies, we are making progress in providing care for the aged in our state. Through united efforts more can be provided. This is our only effective weapon against unsound federal legislation.

It shall be my humble endeavor to merit the confidence so generously given me to fulfill the duties of this important office, and to be guided by the fine example and counsel of my predecessors.

May the New Year bring you and your families happiness and joy.

President, Minnesota State Medical Association

Public Health

NEW PROFESSIONAL NURSING REGULATIONS EXPLAINED

The Minnesota Board of Nursing has published a second notice regarding changes in the laws regulating the practice of professional nursing in Minnesota. All physicians in the state and their office nursing personnel are advised to acquaint themselves with the changes included in the law recently enacted by the Minnesota State Legislature.

The new law provides that after July 1, 1960, only persons having a Minnesota registered nursing license in good standing, or persons who are granted permits pending completion of application for licensure by examination or interstate endorsement are eligible to practice professional nursing for hire in Minnesota.

This does not prohibit the practice of non-professional nursing, usually the sphere of nurse aides, practical nurses or attendants. While there are overlapping functions shared by all persons serving in the nursing field, the higher range of nursing functions and responsibility shall be assigned to and assumed by Minnesota registered nurses only after that date.

As of October, 1959, licenses as registered nurses by waiver have been issued to 186 persons who have met the four regulations listed below.

The regulations are (1) Evidence of good moral character; (2) Evidence of good physical and mental health; (3) Record of at least two years of satisfactory professional nursing employment in Minnesota, and (4) Record of completion of an accredited basic professional nursing education program (accredited by a U. S. or Canadian Board of Nursing during the time the applicant was a student).

The completed application provides for references from registered nurses and official statement of the school of nursing to corroborate the applicant's statement. No written examination is required if the above four requirements are satisfactorily met.

A broader interpretation of the last paragraph of the waiver section of the law will make it possible for additional numbers of persons to be considered as applicants for this licensure during the remaining months of the waiver provisions of the law.

The new interpretation states that nurses who can provide satisfactory evidence of the first three requirements listed above, but who have not completed an accredited basic professional nursing education program (number 4 above) may also apply for this licensure. To these the Board will give a written examination to satisfy itself of their qualifications for registered nurse licensure by waiver.

MORE POLIO VACCINATION NEEDED

About 87 million Americans have now had at least one shot of polio vaccine, and 68 million have had three or more injections, according to new estimates by the Public Health Service.

The figures were released during a day-long meeting Friday of representatives of health and medical organizations who were called here by the Public Health Service to review the 1959 polio experience and to map out ways of promoting further vaccinations before next summer.

Among persons under forty, over 34 million, or almost 30 per cent, have had no vaccine. Among children under five years of age, the group that accounted for 43 per cent of the paralytic cases this year, 4½ million have had no vaccine.

Data from a survey conducted for the Public Health Service by the Bureau of the Census in September, supplemented with data from the National Foundation, form the basis for the new estimates. They indicate that about 14.6 million more people have had some vaccine, and 13.2 million more people have had the recommended dosage of three or more shots since the fall of 1958 when comparable estimates were made.

Plans for a new advertising campaign to be conducted by the Advertising Council and sponsored by the Public Health Service, American Medical Association, and National Foundation were also announced at the meeting. The campaign will be launched in the early spring to support local vaccination drives.

George Earl, M.D., Chairman

PRIVATE MEDICINE AND VOLUNTARY INSURANCE ARE ANSWER TO FORAND BILL

"Uncle Sam With a Stethoscope" was the title of a recent address presented by Dr. Louis M. Orr, President of the American Medical Association, at the 68th Annual Meeting of the Association of Life Insurance Medical Directors of America held at the Hotel Statler Hilton, New York City, October 22, 1959. The following are excerpts from Doctor Orr's address.

"Most of you know, I am sure, that the Forand Bill—which was first introduced in 1957—is being considered by the 86th Congress. This legislation would provide certain hospital, surgical, nursing home and dental benefits to persons receiving Social Security retirement and survivorship payments. The same idea, with numerous variations in benefits and eligibility, will be appearing in many other bills and amendments."

Forand Legislation Involves Basic Principle

"The real issue is not the specific provisions of the Forand Bill, but rather the basic principle involved. Any Forand-type legislation would raise the same danger. It would add service benefits to a Social Security program which so far has been limited to cash payments based on the 'floor-of-protection' concept.

"This new principle, as you know, would alter the nature of the Social Security program. It would pave the way for evolution of a system of tax-paid health care for the entire population. Every two years—in the even years of federal elections—the push for amendment and expansion would be under way. The continuing trend would first undermine, and eventually destroy, our system of voluntary health insurance and the private practice of medicine."

Dangers of Political Appeal Explained

"No action was taken on the Forand proposal during the first session of the 86th Congress. However, it will carry over into the second session. And next year may be a different story. Because of its political appeal, this issue may very well assume 'top priority' status in the presidential election year of 1960.

"From the defensive standpoint, we must be alert to the strategy and tactics which probably will be employed next year by backers of the Forand Bill. For example, we should keep in mind these possibilities:

"They will be ready to accept compromises that will water down the bill.

"They are chiefly interested in establishing a precedent, no matter how small, for government-financed health care of the aged.

"By using the tactics of 'divide and conquer', they will try to prevent the American Medical Association from establishing a united front with the insurance industry, the Blue Plans and the American Hospital Association.

"To disarm physicians, and lessen the intensity of their opposition, the bill may be amended to cover only hospital and nursing home care.

"Every effort will be made to dilute the plan so as to make it more palatable to the hospitals. This strategy may include the suggestion that Blue Cross serve as the fiscal agent for any Social Security hospitalization plan.

"To disarm those who are concerned over the potential cost of the Forand Bill, the age of eligibility may be raised to seventy as a starter."

Beware a "Diluted" Forand Bill

"This different approach will be more dangerous than any outright attempt to pass the Forand Bill as it now stands. A compromise proposal would appear to be harmless and would not open the gate quite so wide right at the start, but it would lead to the same eventualities.

"To counter this approach, we must establish and maintain a united front of physicians, hospitals, insurance companies, Blue Cross, Blue Shield, and all other groups that would be affected by such legislation. It is especially important for hospital administrators and trustees to realize that any kind of government subsidy—either direct from Washington or indirect through a fiscal agent—would simply be the first step toward federal controls."

Medicine and Insurance Industry Solution Necessary

"However, we must do much more than just organize a good defense. We have to show that medicine and insurance have a better answer than the kind offered by Forand-type legislation. Our objective is not simply to beat an undesirable bill in Congress. Our major goal is to help solve a problem. And this particular problem gives us an opportunity for practical action—a challenge to produce dramatic progress in the growth and development of health insurance coverage for older people."

Progress to Date Noted

"Of course, definite progress already had been made before Mr. Forand emerged on the scene with his version of an old idea. As of 1958, some 43 per cent of the people over sixty-five had some form of health insurance protection. Many encouraging activities and trends have been taking shape during the past few years.

"For example, the number of persons over sixty-five

covered by voluntary health insurance has been increasing at a greater rate than the total number of persons reaching age sixty-five.

"Coverage for persons now over sixty-five has been more widely available than generally recognized, but until recently it has not been 'pushed' hard enough by most insurance companies and prepayment plans.

"Continuation after retirement of coverage carried during working years is extending rapidly.

"The principle of paid-up policies at sixty-five is still in the experimental stage, but despite the problems there are several possible ways in which this might be accomplished.

"For the past year or more, both the Blue Shield Plans and the Health Insurance Association of America have had special committees actively studying means of expanding coverage for older persons. The latter organization, as most of you know, has been urging member companies to offer policies that are guaranteed renewable for life, individual and family coverage for persons already over sixty-five, group coverage that will continue after retirement, and group contracts providing the right to convert to individual coverage when employment is terminated."

AMA Takes Action

"To help stimulate all these developments, the House of Delegates of the American Medical Association last December (1958) adopted a proposal which applies specifically to the population group over sixty-five with very modest resources or low family income. For medical services rendered to this particular group, physicians are urged to accept a level of compensation that will permit the development of insurance and prepayment plans at a reduced premium rate.

"Needless to say, the AMA is urging all state and county medical societies to implement that policy of adjusted fees with the utmost speed and vigor. And early this year the Blue Shield Plans developed a model insurance contract for persons over sixty-five, incorporating the principle of the AMA policy action.

"By August, when we testified before the Senate Sub-Committee on Problems of the Aged and Aging, we were able to report that twenty-five Blue Shield plans in twenty-three states now enroll persons over sixty-five. In practically all of the other states, medical societies and Blue Shield plans are working out special new programs for the aged. It also was reported that all Blue Shield plans now permit those over sixty-five to continue their coverage."

Insurance Industry Co-operates

In addition, the commercial insurance companies have been making excellent progress during the past year. An increasing number of companies—including many of you represented here today—either have announced new, specially tailored policies for the aged, or you have extended existing policies to more and more states.

"We can say with truth and confidence that health insurance coverage for the aged will grow at an accelerated pace in the months ahead. In a conservative estimate based on trends of the recent past, the Health Insurance Association of America predicted earlier this year that sixty per cent of the senior citizens who want it or need it will have protection by the end of 1960. Their further estimates are 75 per cent by 1965 and 90 per cent by 1970. Actually, however, because of the intense interest and activity now centering on this problem, the rate of growth might far exceed those conservative predictions—if medicine and insurance will co-operate in a valiant, all-out effort."

Development of Voluntary Coverage for the Aged Is Vital

"During the next nine months or so many people, including the members of Congress, will be paying close attention to the over-all problems of aging and the aged. And while health insurance coverage for older people is only one phase of this broad subject, it is—from a timely, practical standpoint—the most urgent field of activity.

"In my opinion, the medical profession, the prepayment plans and the insurance companies must concentrate in the months ahead on the development of voluntary coverage for the aged. We must promote, advertise and publicize new plans and policies. And we must be able to go before the Congressional committee hearings next spring with a real story to tell—a story of dramatic growth in coverage, new ideas and approaches, and hopeful outlook for future progress.

"If we make that kind of effort, and if we can present a convincing case to Congress next year, I think we may be able to beat back the advocates of government action. If we do not make that effort, I would hesitate to predict the long-range future of medicine and voluntary health insurance."

U. S. CHAMBER OF COMMERCE TAKES ACTION TO OPPOSE FORAND BILL

The Chamber of Commerce of the United States is among the national organizations allied with the American Medical Association, the American Hospital Association, the American Dental Association, the American Nursing Home Association and Blue Cross and Blue Shield in opposing the Forand Bill.

The Insurance Committee of the Chamber of Commerce at its September 17 meeting approved recommendations from its Advisory Committee on Health Insurance for action to strengthen business leadership in combating continuing pressures for compulsory health insurance programs.

The report of the Chairman of the Insurance Committee points out that the proponents of a system of national compulsory health insurance are now concentrating their efforts in two areas. One

involves a plan to amend the social security law so as to give hospital, surgical and nursing home care to our older people, specifically those who are eligible for old-age and survivor benefits. Their plan is set forth in the Forand Bill (H.R. 4700) which is before the Ways and Means Committee. Hearings were held last July and it appears certain that a major effort will be made to pass it next year. The Chamber has opposed this bill.

According to the report, the other major effort of compulsory health insurance advocates is directed toward domination of the White House Conference on Aging, to be held in January, 1961. Already it is apparent that this conference will be made the base for a drive for further government benefits of various kinds for the older people.

The report states that prior to the 1961 White House Conference the law calls for conferences to be held in each state to formulate recommendations to the national conference. Activity is now going on in the states and it appears that the final outcome will be quite well determined at the state and local levels well in advance of 1961.

The advocates of a national system of compulsory health insurance, including the labor unions, welfare workers and others, are working to gain control of these state conferences and their planning committees. Their aim is to get recommendations to the White House Conference favoring compulsory health insurance. Recommendations by the White House Conference favoring a compulsory system would become a powerful influence on Congress to enact such legislation.

The principle, pertinent policy of the Chamber of Commerce of the United States regarding compulsory medical and hospital insurance states:

"The ability of voluntary health insurance to bring a satisfactory measure of protection to practically all the American people is demonstrated in its rapid expansion, wide public acceptance, free competition, experimentation leading to improvements in quality of coverage and method, and progress in insuring aged and impaired persons. Development to its full capacity should be encouraged, but not by payment of a subsidy.

"Proposals for compulsory medical and hospital insurance (socialized medicine) are opposed because their adoption would lower the high standards of medical care in the United States."

The American Medical Association has urged state and county medical societies to co-operate with the Chamber of Commerce in their efforts to oppose compulsory health insurance.

MINNESOTAN URGES PHYSICIAN INSTRUCTION IN PRINCIPLES OF HEALTH INSURANCE

Dr. Haddon M. Carryer, Chairman of the House of Delegates of the Minnesota State Medical Association, recently urged medical schools and medical societies to undertake regular instruction of doctors and students in the use and principles of health insurance.

Doctor Carryer, of the Section of Medicine of the Mayo Clinic, made the suggestion in commenting on the "many problems in common" of the medical profession and the health insurance business.

He addressed the annual Individual Insurance Forum of the Health Insurance Association of America at the Biltmore Hotel in New York City.

Pointing to "The current efforts on the part of both the medical and insurance profession to extend the usefulness of health insurance," Doctor Carryer reported on major common problems toward achieving this goal, and declared:

"These problems are magnified because we are constantly beset by outside planners who would discard gradual evolutionary processes and take a far more radical tack into plans not best for the people whether they be patients or policyholders."

Among problems listed by Doctor Carryer were the costs of processing large numbers of claims, the "failure by patients to understand the nature of the insurance and of benefits to which they are entitled," and not fully understood features of some of the newest types of policies.

"Another problem concerns the matter of indoctrination of physicians with respect to insurance matters," he told the audience of insurance executives. "Instruction should be started in the medical schools with a series of lectures. It should extend to the county medical society and state medical society levels so that physicians understand clearly the significance of such terms as insurance, comprehensive insurance, catastrophic insurance, corridors, deductibles and coinsurance.

"When an insurance program, especially one involving comprehensive care, is introduced in the community, a review of the insurance principles involved should be an integral part of that introduction.

"The omission of such an indoctrination only leads to misunderstanding, over-utilization and bad public relations—bad both for the insurance company and for the physician who may not thoroughly understand insurance principles."

Doctor Carryer praised "the remarkable job that the insurance industry is doing to extend coverage and to make it meaningful to the American people," adding:

"When one considers that this growth is mainly of only fifteen years duration and that now 125 million people have some type of sickness coverage, one can only be amazed at the job that has been accomplished."

EXPERTS PREDICT RISE IN HOSPITAL COSTS; DOCTORS' BILLS WILL HOLD STEADY

The next few years will see hospital costs soaring, doctors' fees holding steady, and medical insurance growing until nearly all the general population is covered for every kind of illness and accident. These predictions, based on extensive interviews with U. S. health officials and physicians, were made recently by *Life* magazine in the concluding article of a series on the American doctor.

The magazine said that it is probably impossible to reduce the costs of running a hospital, but that experts who have studied the problem of skyrocketing prices for hospital care are searching out new paths to efficiency.

In the twenty years from 1936 to 1956 the fees charged by surgeons rose by sixty per cent, those of general practitioners seventy-three per cent. Neither are considered out of line with general price rises. But during the same period, hospital room rates zoomed 265 per cent, faster than almost anything else the dollar can buy. In most hospitals today, private rooms cost about $25 a day.

The *Life* study showed that hospital costs will continue to rise as the result of being forced, among other things, to pay employes better wages. The magazine pointed out that hospitals traditionally have been among the most relentless exploiters of unskilled labor, paying anywhere from $10 to $20 a week less than industry. A hospital strike in New York last spring uncovered the fact that many hospitals were paying their unskilled help weekly salaries of $33.

Two other reasons for bigger bills are the demands by patients for fancier, better decorated rooms, and the fact that nursing care, laboratory and other technical services, which used to take less than half the hospital dollar, today gobble up almost three-fourths of that dollar as new techniques and discoveries enlarge the opportunities for proper medical treatment.

Physician fees will probably remain steady, the magazine said. Thanks to a prosperous economy and the various insurance plans, the hospitals now collect more than 90 per cent of their bills, whereas once they were lucky to collect 75 per cent.

MORE POLIO VACCINATION NEEDED

(Continued from Page 58)

An analysis of the 1959 polio experience made by the Communicable Disease Center of the Public Health Service and reported at the meeting, showed that the vaccine had proved to be at least 90 per cent effective this year in protecting persons who had had three or more doses. In the three cities where major epidemics occurred this year—Des Moines, Iowa, Kansas City, Missouri, and Little Rock, Arkansas—cases were concentrated among unvaccinated persons living in crowded, lower economic areas. A similar pattern occurred in most of the fourteen other cities that reported moderate outbreaks.

After reviewing these and other data, the conference concluded that communities need to start immediately to plan intensive campaigns including surveys to find the neighborhoods where most of the unvaccinated live. They urged that special emphasis be placed on giving vaccinations to infants and preschool children, only 53 per cent of whom have as yet had the recommended schedule of three or more injections. They also urged that all persons who had their third injection a year or more ago get a fourth injection before next summer.

WEAPONS AGAINST TUBERCULOSIS

Early diagnosis.—With the tuberculin test, modern chest x-rays and laboratory tests, unsuspected cases of tuberculosis can be discovered.

Treatment.—Hospitalization until the patient is no longer infectious is usually necessary. The most widely used drugs are isoniazid, streptomycin, and PAS. Sometimes surgery is necessary, too.

Rehabilitation.—Experts help patients to accept and continue treatment until cured; to resume normal, productive living; and to avoid relapse.

Education.—Teaching good health habits to everybody raises the general level of health and so helps increase resistance to tuberculosis.

Research.—Scientists' efforts to find better ways to prevent and cure tuberculosis continue in investigations of immunity, resistance, the nature of the tuberculosis bacillus.

The Art of Medicine

PROFILE OF AN OFFICE ANGEL

Modern diagnostic techniques and equipment have failed to analyze the true success characteristic of the "office angel." *The Bulletin* of the Academy of Medicine of Cleveland recently introduced an article "How to Be the Office Angel" with the following provocative questions.

Is it a pretty face? A sweet voice? Good taste in clothing? Speed at typing?

The article acknowledged that each of these traits is important, but almost any major business executive (and physician) can tell you that none of these is the most important. Some "office angels" lack one or another of these traits. A few lack them all! But in key areas, heavenly secretaries—and their halos—really shine.

1. *Keeping Secrets.*—Sometimes, it's not easy to chat with friends and co-workers without discussing the job, but the best secretaries can do this without revealing any business confidences. The higher a girl rises in position, the more she's apt to know about the business and her boss and the more important her discretion becomes.

2. *Forgiveness.*—To forgive is divine, the saying goes, and the office angel knows it! Sooner or later, a boss is bound to criticize unfairly. The office pest isn't unpleasant out of choice; he doesn't know any better. Strong complaining may make a girl feel good—especially when she knows she's right, but the office angel tries never to build up her ego in this way.

3. *Taking Messages.*—However bright she may be, the ideal secretary never trusts to memory in relaying messages. Instead, she writes the information down; she's too busy to store names and numbers in her mind unnecessarily.

4. *Clock-watching.*—The office angel *is* a clock-watcher; to her, the clock is a useful office tool. It lets her know when a job is taking too long, or, if surprisingly little time has elapsed, it tips her off that she may have forgotten something. She's a calendar-watcher too—keeps a handy little office diary on which to record, among other things, birthdays, anniversaries and such.

5. *Psychology.*—Everyone likes to have his ideas considered, and accepted if possible. So the office angel listens to advice, then takes all the good advice she can (even when offered in the form of a complaint). Even if she was planning to do the thing anyway, she is generous enough to flatter the person by letting him think it was his idea. Why not?

6. *Better Methods.*—The office angel is lazy, but in a very special way. Will a better typewriter ribbon save her work? She'll ask for one as soon as she spots the need. Would she have more time to assist her boss if he'd switch to a dictating machine? She'll suggest the idea, and back up her suggestion with time records kept for two weeks or a month.

7. *Punctuality.*—Nearly everyone in the office comes in and leaves on time, but being punctual means more than this. It means no dragged-out lunch periods, or coffee breaks, or time lapses between different jobs in the office. Spell it "punctuality" or "dependability," the office angel works without having to be watched.

8. *Hope.*—The office angel hopes—and works—not only for her own advancement, but for that of her boss and her company as well. It's an old rule, as true today as ever, that he who gives the most gets the most.

9. *Faith.*—Confidence in the future is a prime characteristic of the office angel. Tactful and skilled in office procedures, she has no cause to worry about her job. If her boss wants to buy a dictaphone dictating machine, she's for it; it's her productivity, not her stenographic skill, she knows, that makes her secure in her job.

10. *Charity.*—Just as rich people give to those less fortunate, the gal who is rich in skills and know-how does what she can to help those who are less experienced or less intelligent. The angel puts in that extra fifteen minutes, now and then, so that a friend may meet her date on time. By watching out for the feelings of others, never lording it over them, helping out—within reason—wherever she can, the office angel stores up treasures in heaven . . . and right here on earth, besides!

Our hats are off to the office angel.

PRESCRIPTION FOR IMPROVING DOCTOR-PATIENT RELATIONSHIP

Members of state and county medical societies who are interested in promoting ideas in improving the relationship between doctor and patient will want to read these remarks by Doctor Paul H. Sullivan, former president, Nassau County Medical Society. They appeared in the organization's *Nassau Medical News.*

If we are to hold to the principle that a patient is entitled to his own physician we must make sure that this actually brings him better medical care than he would get through the "assembly line" methods of group practice, or the service of a "closed panel" hired and paid by someone else.

Our code of ethics provides that "a doctor of medicine is free to choose whom he will serve" but it also states that "he shall not neglect the patient." The personal physician will of course get to know his patient as an individual, but he should also remember the following:

1. Keep your practice covered at all times. If you are planning to be away, make sure some specific person will take your calls. Do not depend upon "service" to find "somebody" to cover your night calls or emergencies. If you are "his" doctor, your patient will expect you to take care of him.
2. Find out whether your patient is insured, and if so, the precise nature of his insurance and how much help he can expect from it.
3. Discuss with him in advance your fee and other financial details such as laboratory services, consultants, *et cetera.* Make sure he understands so that no disputes can arise later.
4. If your patient is covered by a "service benefit" policy approved by the society, he should be given the service. If his policy is for indemnity benefits, you are entitled to set your own fee, but you should avoid "upping" it just because of the insurance. Remember that your patient has been paying premiums for his insurance so he can be protected when the need arises. If insurance is used only as an excuse for higher fees, the whole system of voluntary insurance will break down—and with it perhaps the whole system of "free choice" and "personal physician."
5. If the patient thinks of you as "my doctor," he expects you to think of him as "my patient."

PUBLIC HEALTH EDUCATION COMMITTEE LENDS A HAND

Listener mail response to the WCCO radio shows and the "Doctor, Tell Me" series has been very heavy.

A number of the letters are simple requests for a radio discussion of a particular health topic. Others are diagnostic in their nature and require professional treatment.

Since February, the Public Health Education Committee has included answering these letters as an important phase of their committee function. The quantity of letters which require special attention will often total forty to fifty in number per week.

Medical Legal Opinion

The purpose of this section entitled Medical Legal Opinion is to publish news of recent litigation concerning medical practice as well as to cite past actions and opinions of the Court in medical legal matters as a means of refreshing our knowledge of such procedures.

Minnesota Laws on Practice of Medicine

DEFINITION—PRACTICE OF HEALING—MINNESOTA BASIC SCIENCE LAW

Wherever the term "practicing healing" or "practice of healing" is used in this chapter, unless otherwise specifically defined, the same shall be understood and construed to mean and include any person not hereinafter excepted from the provisions of this chapter, who shall in any manner for any fee, gift, compensation, or reward, or in expectation thereof, engage in, or hold himself out to the public as being engaged in, the practice of medicine or surgery, the practice of osteopathy, the practice of chiropractic, the practice of any legalized method of healing, or the diagnosis, analysis, treatment, correction, or cure of any disease, injury, defect, deformity, infirmity, ailment, or affliction of human beings, or any condition or conditions incident to pregnancy or childbirth, or examination into the fact, condition, or cause of human health or disease, or who shall, for any fee, gift, compensation, or reward, or in expectation thereof, suggest, recommend, or prescribe any medicine or any form of treatment, correction, or cure thereof; also any person, or persons, not hereinafter excepted from the provisions of this chapter, individually or collectively, who maintains an office for the reception, examination, diagnosis, or treatment of any person for any disease, injury, defect, deformity, or infirmity of body or mind, or who attaches the title of doctor, physician, surgeon, specialist, M.D., M.B., D.O., D.C., or any other word, abbreviation, or title to his name indicating, or designed to indicate, that he is engaged in the practice of healing.

(Section 146.01—Minnesota Statutes 1957)

A violation of the Minnesota Basic Science Law is a gross misdemeanor and punishable by a fine of not to exceed $1,000 or not to exceed one year in jail.

(Section 146.17—Minnesota Statutes 1957)

DEFINITION—PRACTICE OF MEDICINE—MINNESOTA MEDICAL PRACTICE ACT

Every person not heretofore authorized by law so to do who shall practice medicine in the state without having obtained the license herein provided for, and every person who shall so practice contrary to any provision of this chapter, shall be guilty of a gross misdemeanor. Any person shall be regarded as practicing within the meaning of this chapter who shall append the letters M.B. or M.D. to his name, or for a fee prescribe, direct or recommend for the use of any person, any drug, or medicine or other agency for the treatment or relief of any wound, fracture, or bodily injury, infirmity, or disease.

(Section 147.10—Minnesota Statutes 1957)

Splitting Fees Unlawful.—It shall be unlawful for any physician or surgeon to divide fees with, or to promise to pay a part of his fee to, or pay a commission to, any other physician or surgeon or person who calls him in consultation or sends patients to him for treatment or operation.

(Section 147.11—Minnesota Statutes 1957)

Punishment for Violation.—Any physician or surgeon who pays or receives any money prohibited by section 147.11 shall be punished by a fine of not to exceed $100 or by imprisonment in the county jail for not to exceed ninety days.

(Section 147.12—Minnesota Statutes 1957)

Revocation of License.—In case a physician or surgeon shall be convicted of violating any of the provisions of section 147.11, the state board of medical examiners, upon a first conviction, may, and, upon a subsequent conviction, shall, revoke the license of the person so convicted, but such revocation shall be subject to the right of the person whose license has been so revoked to appeal to the district court of the proper county on questions of law and fact.

(Section 147.13—Minnesota Statutes 1957)

INTERPRETATION OF STATUTES—DEFINITIONS OF WORDS AND PHRASES

Person.—"Person" may extend and be applied to bodies politic and corporate, and to partnerships and other unincorporated associations.

(Section 645.44, Subd. 7—Minnesota Statutes 1957)

DEFINITION—NON-PROFIT HOSPITAL SERVICE PLAN CORPORATIONS

(Blue Cross Law—Minnesota.)

Non-profit Hospital Service Plan Corporations.—Any corporation organized under the laws of this state, on a strictly non-profit basis, for the purpose of establishing and operating a non-profit hospital service plan whereby hospital service is provided by hospitals with which such corporation has a contract, to persons who become subscribers to the plan under a contract with such corporation for such hospital service shall be subject to, and, governed by the provisions of sections 309.10 to 309.17 and shall not be subject to the laws of this state relating to insurance and insurance companies, except as hereinafter specifically provided.

(Section 309.10—Minnesota Statutes 1957)

May Provide Service in Non-member Hospitals.—The hospital service plan operated by such corporation, may also provide for hospital service to such subscribers in other than contracting hospitals, in case of emergency or expediency, and subject to the approval of the governing body of such hospital service plan corporation.

(Section 309.11—Minnesota Statutes 1957)

Not to Engage in Medical Practice.—Nothing herein shall authorize any person, association, or corporation to engage, in any manner, in the practice of healing, or the practice of medicine, as defined by law.

(Section 309.17—Minnesota Statutes 1957)

DEFINITION—VOLUNTARY NONPROFIT MEDICAL SERVICE PLAN CORPORATIONS

(Blue Shield Law—Minnesota.)

Purpose.—It is the purpose and intent of this chapter, and the policy of the Legislature, to make possible a wider and more timely availability of medical care, thereby advancing the public health and the science and art of medicine in this state.

(Section 159.01—Minnesota Statutes 1957)

Incorporation and Organization.—Nonprofit medical service plan corporations hereinafter incorporated may be organized under and in accordance with the provisions of this chapter by not less than twenty-one persons, all of whom shall be legal residents of this state and duly licensed and registered doctors of medicine under the laws of this state.

Such nonprofit medical service plan corporation shall have the right to establish, maintain, and operate a voluntary nonprofit medical service plan, whereby the services of duly licensed and registered doctors of medicine and dentistry are provided in the manner hereinafter specified at the expense of such corporation to persons who become subscribers to said plan under contracts which entitle such subscribers to specified medical, surgical and dental care, appliances and supplies, by such duly licensed and registered doctors of medicine and dentistry. Such medical, surgical and dental care, appliances and supplies may be provided in their entirety or in part as such corporation may determine and as set forth in such contracts. The term "subscribers" shall include all persons covered under such contracts.

All such nonprofit medical service plan corporations shall be subject to and governed by the provisions of this chapter, and shall not be subject to the laws of this state relating to insurance and insurance companies, except as hereinafter specifically provided.

No such medical service contract by or on behalf of any such nonprofit medical service plan corporation shall provide for the payment of any cash indemnification by the corporation to the subscriber or his estate on account of death, illness or other injury.

(Section 159.02—Minnesota Statutes 1957)

DEFINITIONS—HOSPITALS—HOSPITALIZATION—MINNESOTA

Hospitals, Licenses, Definitions.—No person, partnership, association, or corporation, nor any state, county, or local governmental units, nor any division, department, board, or agency thereof, shall establish, conduct, or maintain in the state any hospital, sanatorium, rest home, nursing home, boarding home, or other institution for the hospitalization or care of human beings without first obtaining a license therefor in the manner hereinafter provided.

Hospital, sanatorium, rest home, nursing home, boarding home, and other related institutions, within the meaning of sections 144.50 to 144.56 shall mean any institution, place, building, or agency in which any accommodation is maintained, furnished, or offered for the hospitalization of the sick or injured or for maternity care of more than one woman within a period of six months or for care of three or more aged or infirm persons requiring or receiving chronic or convalescent care. Nothing in sections 144.50 to 144.56 shall apply to hotels or other similar places that furnish only board and room, or either, to their guests.

"Hospitalization" means the reception and care of persons for a continuous period longer than twenty-four hours, for the purpose of diagnosis or treatment bearing on the physical or mental health of such persons.

"Maternity care" means the care and treatment of a woman during pregnancy or during delivery or within ten days after delivery, and for the purposes of sections 144.50 to 144.56 shall include

AMA Report Discloses Status of Medical Education

The Council on Medical Education and Hospitals of the American Medical Association, in its annual comprehensive report on all aspects of medical education, announced that the 1958-59 graduating class receiving the M.D. degree numbered 6,860, only one less than in 1957-58.

These two classes were the largest except for the 1954-55 year when the class was 6,977. The increase in that term was occasioned by including as graduates the fifty students completing the intern year then required by Stanford University.

Forty-three medical schools had decreases in the number graduated while thirty-four schools experienced increases.

Women comprised 5.4 per cent of the graduating class and comprised 5.9 per cent of the Canadian 1958-59 graduating class.

Need For Adequate Medical Education Opportunities Grows

Much of the council's report dealt with educational opportunities for the number of medical students considered adequate to satisfy medical service needs in a vastly growing population.

"To accomplish this task and at the same time maintain high standards of medical education represents a challenge at least as important as any problem facing medicine today," the AMA report said.

The council indicated a need for 10,000 graduates a year from medical schools in the United States by 1975.

"The fundamental issue," the report said, "does not involve the question of which of various studies have resulted in the most accurate estimate of the need for increased numbers of medical school graduates. The basic and urgent concern is that all estimates indicate a need for expansion of educational facilities in medicine in a brief period which far exceeds any expansion of such facilities that has occurred in a similar period during modern times."

The council offered several methods which could be used to meet the need for expanded educational facilities in medicine, including increased capacity of existing medical schools, but then added:

"Care must be exercised that medical schools not be induced to expand beyond their capacity to maintain the proportionately increased teaching staff necessary to preserve high standards of education and research."

New Medical Schools Needed

The council estimated that even though existing schools are expanded, "it appears likely that at least ten new schools with an average graduating class of one hundred students will be required" to meet the health care needs of an exploding population.

On the subject of medical students of the future, the council said:

"Medicine is finding increased competition for the pool of top-ranking students because it no longer occupies the unique position as a profession which it held in the past and shared largely only with law and the ministry. The professions open to the college graduate are now much broader, and they provide the prestige, intellectual satisfaction, and financial rewards comparable to those offered by medicine."

The council cautioned:

"Medicine must make active efforts to inform young people of the breadth of interests and challenges it offers or surely it will suffer a serious loss of the best young talent."

Other important points in the council's report are:

The total enrollment in first year medical school classes for the 1958-59 academic year was 8,128, the largest to date in the United States. Entering class sizes increased in thirty-five schools, were unchanged in twenty-four, and decreased in twenty-six.

In 1958-59, a total of 59,102 applications were filed by 15,170 persons or an average of 3.9 applications made by each prospective medical student.

Of all first-year medical students, more than one-third, 37 per cent, came from five states: New York, Pennsylvania, California, Ohio and Illinois.

At least two-thirds of the entering classes comprise "B" average students. About one-sixth had college grade averages of "A" and about one-sixth to one-seventh had "C" averages.

AHA ANNUAL SCIENTIFIC SESSIONS SET NEW ATTENDANCE RECORD

A new attendance record of more than 5,000 physicians, scientists and lay leaders was set at the 1959 Annual Meeting and Scientific Sessions of the American Heart Association in Philadelphia, October 23-27. This figure compares with 3,375 who attended the 1958 meetings in San Francisco.

Interest in the scientific program this year was heightened by daily sessions on clinical cardiology, a joint program with the American College of Cardiology, a special session for nurses, and an address by Secretary Arthur S. Flemming of the U. S. Department of Health, Education and Welfare on "The Role of Voluntary Health Associations in Meeting Future Health Needs."

Report from Dallas . . .

Important Actions Taken by AMA House of Delegates

Freedom of choice of physician, relations between physicians and hospitals, a scholarship program for deserving medical students and relative value studies of medical services were among the major subjects acted upon by the House of Delegates at the American Medical Association's Thirteenth Clinical Meeting held December 1-4 in Dallas.

Total registration through Thursday, with half a day of the meeting still remaining, had reached 4,727, including 2,742 physicians.

Freedom of Choice

In considering four resolutions which in various ways would have changed or replaced the statements on freedom of choice of physician which the House adopted in June, 1959, when acting upon the recommendations in the report of the Commission on Medical Care Plans, the House reaffirmed the following two statements approved in Atlantic City:

1. "The American Medical Association believes that free choice of physician is the right of every individual and one which he should be free to exercise as he chooses."
2. "Each individual should be accorded the privilege to select and change his physician at will or to select his preferred system of medical care, and the American Medical Association vigorously supports the right of the individual to choose between these alternatives."

However, in order to clarify and strengthen its position on the issue of freedom of choice of physician, the House also adopted this additional statement which was submitted as a substitute amendment on the floor of the House:

3. "Lest there be any misinterpretation, we state unequivocally that the American Medical Association firmly subscribes to freedom of choice of physician and free competition among physicians as being prerequisites to optimal medical care. The benefits of any system which provides medical care must be judged on the degree to which it allows of, or abridges, such freedom of choice and such competition."

Physician-Hospital Relations

The House received twelve resolutions on the subject of relationships between physicians and hospitals. To resolve any doubt about its position, the House did not act upon any of the resolutions but instead reaffirmed the 1951 "Guides for Conduct of Physicians in Relationships with Institutions." It also declared that "all subsequent or inconsistent actions are considered superseded."

The House also accepted recommendations that (1) the House of Delegates acknowledge the need to strengthen relationships with hospitals by action at state and local levels, (2) the Board of Trustees of the Association continue to maintain liaison with the Board of Trustees of the American Hospital Association, and (3) the Council on Medical Service review this entire problem to ascertain if there have been actions inconsistent with the 1951 Guides.

Those Guides summarize the following general principles as a basis for adjusting controversies:

1. "A physician should not dispose of his professional attainments or services to any hospital, corporation or lay body by whatever name called or however organized under terms or conditions which permit the sale of the services of that physician by such agency for a fee.
2. "Where a hospital is not selling the services of a physician, the financial arrangement if any between the hospital and the physician properly may be placed on any mutually satisfactory basis. This refers to the remuneration of a physician for teaching or research or charitable services or the like. Corporations or other lay bodies properly may provide such services and employ or otherwise engage doctors for those purposes.
3. "The practice of anesthesiology, pathology, physical medicine and radiology are an integral part of the practice of medicine in the same category as the practice of surgery, internal medicine or any other designated field of medicine."

Scholarship Program

To help meet the need for an increasing number of physicians in the future, the House approved the creation of a special study committee which was asked to:

1. Present a scholarship program, its development, administration and the role of the American Medical Association in fulfilling it.
2. Ascertain the maximum to which medical schools could expand their student bodies while maintaining the quality of medical education.
3. Ascertain what universities can support new medical schools with qualified students and sufficient clinical material for teaching—either on a two year or a full four year basis.
4. Investigate the securing of competent medical faculties.
5. Investigate financing of expansion and establishment of medical schools.
6. Investigate financing of medical education as to the most economical methods of obtaining high quality medical training.
7. Develop methods of getting well-qualified students to undertake the study of medicine.
8. Investigate the possibility of relaxing rigid geographic restrictions on the admission of students to medical schools.

The House urged that the special committee be implemented promptly with adequate funds and

staff so that it may make an initial report by June, 1960.

Relative Value Studies

Reaffirming a previous policy statement, the House approved in principle the conducting of relative studies by each state medical society, rather than a nationwide study of a series or regional studies by the A.M.A. The House also reiterated its authorization for the Committee on Medical Practices to inform each state medical association, through regional or other meetings, of the purpose, scope and objectives of such studies, the steps to be followed in conducting studies, the problems which may be encountered and the manner in which the results can be applied.

The House recognized, however, that some state medical societies are either not interested in relative value studies or are actively opposed to them. It pointed out that some state medical associations fear that the regional conferences of the Committee on Medical Practices will put pressure on them to carry out such studies and that this will result in the adoption of "fixed fees."

Since the regional conferences are educational in nature, the House said, it remains for each state or county medical association to accept or reject the idea of a study in its area.

The House expressed awareness of the fact that this is still a controversial matter. However, it commended the Committee on Medical Practices for its effort to carry out the instructions of the House, and it urged the committee to continue its educational work.

Miscellaneous Actions

In considering forty-four resolutions and a large volume of annual, supplementary and special reports, the House also:

Learned that the AMA Board of Trustees has appointed a liaison committee to meet with a similar committee of the *American Osteopathic Association* to consider matters of common concern;

Emphasized that local medical societies should insure that no member violates ethical traditions as they relate to ownership of pharmacies or stock in pharmaceutical companies;

Called for investigation of the need, desirability and feasibility of establishing a home for *aged and retired physicians;*

Suggested that fees for consultative examinations under programs of the *Bureau of Old Age and Survivors Insurance* should be adjudicated directly between the state medical society and the state agency involved;

Registered a strong protest to the *Veterans Administration,* urging stricter screening of non- service-connected disability patients admitted to government hospitals;

Reiterated the Association's support of the *Blue Shield* concept and directed the Council on Medical Service to submit at the June, 1960, meeting its recommendations concerning a policy statement on A.M.A. relationship with Blue Shield plans;

Urged that *medical schools* include in their curricula a course on the social, political and economic aspects of medicine;

Suggested that the AMA make available to school libraries *information and literature* showing the advantages of private medical care and the American free enterprise system;

Recommended that all state and county medical societies establish programs for the inspection and testing of all *fluoroscopes and radiographic equipment;*

Called upon each individual physician to wage "a vigorous, dynamic and uncompromising fight" against the *Forand type of legislation;*

Urged state and local medical societies and individual physicians to implement the AMA program for recruitment of high-grade *Medical students;*

Reaffirmed the "Suggested Guides to Relations Between Medical Societies and *Voluntary Health Agencies,*" which were adopted at the December, 1957, meeting in Philadelphia.

At the Tuesday opening session, six state medical societies presented nearly $250,000 to the American Medical Education Foundation. The checks turned over to Doctor George F. Lull, President of AMEF were; California, $156,562; Indiana, $35,570; New York, $19,546; Utah, $10,355; New Jersey, $10,000 and Arizona, $9,263.

MEDICAL LEGAL OPINIONS

(Continued from Page 66)

care during such period of time of the infant born to such mother.

"Chronic or convalescent care" means (1) care required by a person because of prolonged mental or physical illness or defect or during recovery from injury or disease and shall include any or all of the procedures commonly employed in caring for the sick; and (2) care incident to old age required by a person who because of advancing age is not capable of properly caring for himself and shall include necessary personal or custodial care. The furnishing of board, room, and laundry shall not in itself be deemed care incident to old age.

Nothing in sections 144.50 to 144.56 shall authorize any person, partnership, association, or corporation, nor any state, county, or local governmental units, nor any division, department, board, or agency thereof, to engage, in any manner, in the practice of healing, or the practice of medicine, as defined by law.

(Section 144.50—Minnesota Statutes 1957)

A violation of the above law is a misdemeanor punishable by a fine and a jail sentence.

(Section 144.49, Subd. 7—Minnesota Statutes 1957)

History of Medicine in Minnesota

PIONEER PHYSICIANS OF STEVENS COUNTY, MINNESOTA

JOSEPHINE EDDY, GRACE HALL
A. I. ARNESON, M.D.
Morris, Minnesota

ROBERT ROSENTHAL, M.D.
Saint Paul, Minnesota

(Continued from October 1959 issue)

Dr. Charles L. Gates seems to have practiced in Morris before graduation from a medical school. His professional card published on November 23, 1876, read: "Dr. C. L. Gates, Physician and Surgeon, Office hours: Morris 8:30-9:30 A.M. Office in Benson on 4th Street," and a newspaper item of August 25, 1876, reports the amputation of a thumb of a very sick lady by Dr. Gates. He graduated from the Medical College in Cincinnati, Ohio, in 1877, and was a homeopath. After his graduation he came to St. Paul and pursued his medical studies for nearly three years with Dr. C. G. Higby.†

Then he went to Benson, Swift County, and settled down to the practice of medicine. Supposedly, he was in Benson for nine years, but as he moved to Hancock in 1883 it seems very unlikely that he was nine years in Benson even if his practice prior in 1877 is included. His practice then developed into an extensive one. He was very active in all public affairs and educational and religious matters. He organized the first Sabbath School and prayer meeting in Benson.

In 1883 Dr. Gates came to Hancock where he already had a large business. He ranked high in that community as a physician because of his excellent character and his integrity. He was the first physician to locate in Hancock.

Dr. Gates was born in Tioga County, New York, on June 11, 1847, the son of Lattimer B. and Elizabeth (Sanford) Gates, both natives of the state of New York. As mentioned, he received his medical schooling at the Medical College of Cincinnati, Ohio, from which he graduated in 1877. He was licensed to practice in Minnesota as a homeopath on December 31, 1883. His preceptor in St. Paul, Dr. Higby, also practiced homeopathic medicine. An old timer remembered § that when he was a child Dr. Gates came to treat his seriously ill brother. He drove a team of rather small speckled ponies and apparently made his calls whenever the notion struck him, though he did not seem to charge for all of them.

Dr. Gates was medium tall, of slight build, had rather sharp eyes and a clipped beard. He spoke in a very quiet, low voice supposedly because of his deafness. He always carried a small black satchel containing his drugs. The doctor usually left two small glass vials, each about two inches long, one of which contained a water-like liquid and one a powder very much like sugar.

---

†Dr. Chester Goss Higby (1835-1908) was, like Dr. Gates, born in the state of New York. He graduated from the Hahnemann Medical College Hospital, Chicago, in 1870. He first practiced in Red Wing, but moved to St. Paul in 1873 or 1874. He was very active in the affairs of homeopathic societies.

§Communication of Joe E. O'Neil, Morris, Minnesota, March, 1956.

Dr. Gates seems to have developed a successful practice and he was called long distances from Hancock to treat seriously ill patients. It seems his old patients were loyal to him and it is known that at least until 1890 he made regular visits every Friday to Benson, where he had practiced before coming to Hancock. His loyalty to, and trust in, his old preceptor, Dr. Higby, is shown by the fact that at least once he called him as consultant to Stevens County and that he put himself under Dr. Higby's care when he was very ill in the winter of 1892-1893. This illness had started in the first half of December, 1892; in January, he went to St. Paul to Dr. Higby. His illness gave rise to a great deal of anxiety among his friends, and he did not begin to resume practice until March, 1893.

Dr. Gates married Harriet E. Cook at Benson on August 27, 1879. In political matters he was a Republican. He belonged to the Congregational Church. His death came suddenly; he was killed by a train on June 9, 1910, while he walked along the railroad. No doubt his deafness was a contributing factor.

Dr. William M. Goucher came to Morris in 1878. His professional card appeared in the *Stevens County Tribune* of July 4, 1878: "Dr. W. M. Goucher, office at Teel's Drug Store. Residence, Perkins Hotel, Morris, Minnesota."

The memories of his practice in Morris are not pleasant due to an occurance a year after he came there. It is difficult at this time to judge the case impartially. The *Stevens County Tribune* of July 4, 1879, related the story of a criminal attack on a girl of "good character" who, on the way from Herman, Grant County, passed through Morris and became ill with what the physician who treated her called a "bilious fever." The story goes on to tell that Dr. Goucher forced his way into her room during the night, told her not to take any more of the first doctor's medicine, and then assaulted her. Dr. Goucher was jailed, but later released for lack of evidence. In September, the same newspaper tells that the girl never left her bed after the attack and that the excitement and fright threw her into a dangerous fever. The newspaper seems to be convinced of his guilt.

It is difficult to accept this case as it appears in the papers, although it is true that Dr. Goucher had the reputation of intemperate habits. There is a story that a farmer near Morris needed help in threshing and Dr. Goucher offered to help him. After a few hours of good work, two of his cronies arrived with a bottle of whiskey, the three retired behind a straw-stack and from then on the doctor was of little help. He was a man of medium size, reddened face and very muscular. He was a friendly person and always kind to children, though he seemed to associate more with the rougher elements. All this may be a reason why many people thought he might not be incapable of committing the deed of which he was accused. The circumstances of the supposed crime—the girl suffered from a "bilious fever"—and the long "dangerous fever" following the deed—seem to throw some doubt on the whole affair. One wonders whether a psychiatric examination of the patient could have shed some more light on the incident.

It seems he continued to practice in Morris, as we find his professional card in November, 1880: "W. M. Goucher, physician and surgeon. Consultation in German and English. Office over Helgeson and Hanson's Store, Atlantic Ave., Morris, Minnesota." But in April, 1881, a newspaper reported recovery of an injured patient who was successfully operated on by Dr. Goucher of Graceville, Big Stone County: He is considered the first physician to locate in Graceville.

In October of that year, he advertised in a Morris newspaper, giving his address in Graceville. On April 13, 1882, he is again reported in Morris: "He is about to open an office and resume practice at this place," and in June he is reported to have purchased the building in which his office was located. In

September, 1882, his card reads ". . . office at his residence on Pacific Ave., Morris . . ."

Dr. Goucher left Morris again in October, 1884, to locate once more in Graceville. Polk's Medical Directory lists him as practicing in Graceville in 1886. In the spring of the same year we learn that he died suddenly from vascular heart disease (*Graceville Transcript,* April 1, 1886). His wife came from St. Paul too late to see him before he was placed in the casket. One may speculate whether she was just visiting in St. Paul or whether they were separated. It seems he was not a successful physician, because the newspaper states that "friends provided a neat suit of garments" for his funeral. He was buried in the Protestant cemetery.

Not much is known of Dr. Goucher's background. It seems he came originally from the East, because in September, 1882, he returned from the East where he visited his aged parents. During the Civil War he served as Army surgeon. Nothing is known of his medical education. After the Minnesota Medical Act went into effect, he was authorized to practice under the "years of practice section."

Dr. Thomas E. Heenan came to Stevens County in 1878. He was born in Philadelphia on March 29, 1849. His medical education was received at the Medical Department of the University of Pennsylvania, where he earned his M.D. degree. He came to Stevens County in April, 1878, with the idea of doing big farming. His professional card—"Thomas E. Heenan, physician and surgeon, Morris, Minn."—appeared as early as April, 1878. It seems he did not become established at once, because a newspaper item of February 6, 1879, states that he returned a few days before (apparently from a visit to the south of the state) and that he is going to open an office in the village and practice his profession. He did not neglect, however, his primary interest—farming—and had 500 acres ready for seeding by the end of March, 1879. Soon he also owned one of the finest stallions in the county.

It seems he did not open a regular office, or that he opened a new one, as a news item of March 4, 1880, states that he "is about to open an office in this village and has engaged the front rooms in Christensian's building which he is having fitted and furnished in metropolitan style." By the end of March, his office was actually being used. There is no doubt, however, that he practiced from at least 1879 on. His is the honor of having written prescription No. 1 of the drugstore which is now the Arneson Drugstore. It is dated February 26, 1880, and called for pills of quinine sulphate. Many newspaper items between 1880 and 1884 attest that his medical services were frequently used in severe cases.

Dr. Heenan was of aristocratic appearance. He was tall and slender with dark eyes and wavy dark hair. In winter, he wore a buffalo coat made of the finest dark skins. He was a bachelor.

In politics he was a Democrat. In an article published June 27, 1884, the following appears:

> "The Democrats of Stevens County are to be congratulated upon the recognition they have received in the recent state convention in the election of Dr. Thomas E. Heenan as one of the delegates from the Fifth District to the Chicago Convention. No more fitting representative of the young and earnest democracy of the State could have been chosen and that he was so chosen is due entirely to his own personal qualities and their recognition by the Democrats of the district. Stevens County will have a voice in naming the next President of the United States."

Besides his political activities, practicing his profession and farming, Dr. Heenan held the offices of commissioner of bridges on the Pomme de Terre River, county auditor, and surgeon for the Northern Pacific Railroad in Stevens County.

He was endorsed by both Republican and Democratic newspapers in Minnesota as United States Minister to Sweden. This position did not materialize, but in the November 5, 1885, issue of *The Sun,* the appointment of Dr. Heenan as U. S. Consul to Odessa, Russia, was announced. It pays tribute to him as an able physician and to his popularity, as shown in part by his election as county auditor. It quotes the *St. Paul Globe,* which states, among other points, that "He is recognized as a good physician and a man of sound character and judgment." A forcible message to Dr. Heenan was printed in the *Sun* of December 17, 1885.

The appointment as Consul to Odessa is actually dated October 29, 1885. It seems that he was well fitted for this diplomatic post, because he was later (March 30, 1907) appointed Consul General at Newshwang, China, and Consul on June 10, 1908. In January, 1909, he became Consul at Warsaw, Poland, and on April 24, 1914, Consul at Fiume, Hungary. At this last post he did not assume charge until June 24, and the very next day—on June 25, 1914—he died of a heart attack.§

It seems his only surviving relative was a sister, Mrs. St. Clair Mulholland of Philadelphia.

Dr. William E. Holden came to Morris in 1875. His professional card on November 23, 1876, read: "Wm. E. Holden, M.D., Physician and Surgeon. Residence, Pacific Avenue, Morris, Minn. Professional calls attended both day and night. Patients from abroad can be accommodated with board." He took the place of Dr. E. R. Wait.

The *Stevens County Reporter* of March 31, 1877, lists him among the professional men as the only physician in Morris.

His practice took him to Hancock and Benson, Swift County, but it is very doubtful that he actually located there. In March, 1878, he moved to Glenwood, Pope County. There he lived in a small house which he also used as a sort of drugstore. His wife ran a boarding and lodging house in the same building. Because of insufficient space, he moved his drugs to the Bartke Hall and established there a drugstore—the first real drugstore in Glenwood. It seems he was active in civic affairs in Pope County. In 1878 he was elected county coroner and held this position until he left the county. He was also justice of the peace in Glenwood. In the fall of 1879 his store of drugs was moved into the H. N. Rue store, and Dr. Holden left the county. Mr. Rue took over Dr. Holden's drug business and Dr. Holterman his practice.† According to a newspaper item of February 19, 1880. Dr. Holden located at Herman, Grant County. He is listed there through 1890 but in 1893 we find him in Ashby, Grant County, and that is the location he gave when he received his Minnesota license, according to the *"Official Register, Physicians in Minnesota, 1883-1890."*

He was born in New Hampshire; his wife in Indiana. A son was born to them in Glenwood in February, 1878. Nothing is known of his medical background, nor when and where he died.

---

§The information about his diplomatic career was supplied by the National Archives and Records Service in Washington, D. C. (10/3/1956).

†From an unpublished biographical sketch by Mr. Roy Skinner (1936), Pope County.

He was born in New Hampshire; his wife in Indiana. A son was born to them in Glenwood in February, 1878. Nothing is known of his medical background, nor when and where he died.

Dr. Horton evidently practiced medicine in Hancock, in the year 1886 as the following item appeared in the local paper May 20, 1886: "Our physician, Dr. Horton, understands his business and is meeting with good success. All who require his services need not fear placing their case in his hands."

In January of 1887, Dr. Horton contracted typhoid fever and passed away from the disease. On January 13, 1887, the following item appeared in the local news:

"The funeral of Dr. Horton took place today from the Merchant's Hotel. The parents of the deceased were in attendance. For sanitary reasons, the fatal disease—typhoid fever—being considered contagious, the parents were not allowed to remove the remains to their residence for burial."

Nothing more is known about him, not even his first name.

Dr. H. L. Hulburd was born in Lawrenceville, New York, September 1, 1851. His father was Lucius Hulburd, a native of Vermont. His mother, before her marriage, was Cordelia Whittemore, also a native of Vermont.

Dr. Hulburd was graduated from Lawrenceville Academy in 1875. He was married June 22, 1873. After graduation they moved to Prescott, Wisconsin, where he practiced two years, moving to Morris in 1878.

In appearance, Dr. Hulburd was a rather small man with sandy colored hair. He sometimes let his beard grow in the winter when he had driving to do. It was heavy and decidedly red. He was always well groomed. He liked flowers and in season wore a small white myrtle flower in his buttonhole. He drove an old fashioned Boston chaise which he used for professional driving and family use. He was a kindly quiet man, one to inspire confidence by his manner. In the years of adversity which struck Stevens County soon after the arrival of Dr. Hulburd, no call for help ever came to him to which he did not respond. He was painstaking and liberal with his services and gave freely to charity.

His favorite prescription for children was Castoria, accompanied by candy or a penny. Besides his regular practice he extracted teeth—charging fifty cents for one extraction. His name is signed to prescription No. 3 in the files of the present Arneson Drug Store in Morris. Dr. Hulburd conscientiously kept abreast of the times, making special study of the use of the x-ray. He was offered the x-ray work in a large hospital in Los Angeles, California. In 1895 he went to New York and "took a course in lung treatment and expects to make that a specialty; also the cure of that dreadful disease, consumption," according to the *Morris Tribune*.

Dr. Hulburd was a member of the Congregational church of Morris and was very active in church work. He was a trustee for many years. In political life he was a Republican. He belonged to the Masonic, Maccabees and United Workmen's Lodges. He was the last charter member of the Morris Workmen's Lodge living in Morris at the time of his death. He was a member of the American Medical Association, the Minnesota State Medical Society, the West Central Medical Society, and was very prominent in medical circles in this section of the state. He was county coroner and county physician for many years and was holding the position of county physician at the time of his death. He was also a member of the pension medical examining board.

Dr. Hulburd experimented for some time with a telephone and finally had one connected between his residence and Moore's Drug Store in August, 1879, the first telephone in the village.

Dr. Hulburd died at his home, Saturday afternoon, May 16, 1916, after an illness of several weeks with blood poisoning in his left hand, contracted while caring for a patient. The news of his death cast a gloom over the whole city. The funeral was held in the home as the doctor had requested. From three until four o'clock the business houses of Morris were closed as a token of respect for the memory of the beloved physician. He was buried in the Morris Summit Cemetery. He was survived by his wife, Margaret, and one daughter, Cora.

Many were the expressions of regret and sorrow at his passing in the *Morris Tribune* of May 19, 1916. Frank Hancock wrote:

"Dr. Hulburd was one of the best men I have ever known. He was a man of noble impulses who gave freely of his time and money to the distressed. His deeds of charity will never be known. He was a high grade citizen in every respect." And E. J. Jones: "He was one of the best men I have known anywhere. He was most unselfish, kind and generous and was always looking for an opportunity to do good. Words fail to do justice to his memory."

A teacher who taught in Morris in the early 1900's and for several summers helped him in his office wrote in a letter:

". . . he had sense of humor, a kind heart and was the finest type of Christian gentleman . . . he was respected, admired but especially loved. . . ."

Dr. Henry Peter Johnson practiced in Hancock up to 1882.* It is not known when he came there but, as he graduated from Rush Medical College in 1879, he probably came there around 1880. Dr. Johnson was born on February 3, 1855, near Oshkosh, Wisconsin, and as an infant moved with his family to the settlement of Pleasant Hill, Fremont township, in Winona County, Minnesota. His early education he received in Houston County and in Winona. After teaching two terms of school, he entered Rush Medical College in Chicago from which he graduated, as mentioned, in 1879.

In 1882 he moved to the village of Houston, Houston County. He practiced there for ten years and was county coroner for a number of years. In 1892 he moved to La Crosse, Wisconsin. After four years there, he moved to Long Prairie, Todd County, and finally to Fairmount, Martin County. There he owned and operated the Johnson Hospital for several years. He died in Fairmount on March 31, 1943.

Dr. George M. Lambert was in Morris only a few months. His professional card appeared in the local paper in June, 1877, stating that he was "late surgeon 4th Regiment, Minn. Volunteers, Morris, Minn. Professional calls promptly attended to by day or night." He died on August 30 of the same year at the tragically early age of thirty-six. One is justified in assuming that the illness which caused him to resign his position as prison physician at Stillwater—"Dropsy of the heart"—was the cause of his death. He was buried at Morris, but later exhumed at the request of his wife and transferred to St. Paul.

Dr. Lambert was born in the state of New Jersey in 1841, the son of Judge Henry A. Lambert of St. Paul. He had come to Minnesota when he was very young and received a good education. He graduated from Georgetown College,

*From the extended biographical sketch in "Notes on the History of Medicine in Houston County prior to 1900" by Nora H. Guthrey: Minnesota Medicine, 38:931 and 1005 (Nov. and Dec.) 1955.

Washington, D. C., and later from Miami Medical College, Cincinnati, Ohio. Soon after that** he was appointed surgeon of the 4th Minnesota Infantry Volunteers and served through the entire Civil War. When he returned† he became physician at the prison at Stillwater, from which position he had to resign because of illness.

Dr. Charles Laurel.—A news item appeared in the local paper on September 30, 1880, as follows: "Dr. Charles Laurel, an M.D. from Kansas,‡ has arrived in Morris and contemplates locating here permanently. The doctor converses in English, German and Scandinavian." Evidently the doctor located in Benson, Swift County, instead, or stayed only a very short time in Morris, as on June 30, 1881, the following business notice appeared in the paper: "Dr. Charles Laurel of Benson will visit Morris the first, second and third days of each month."

However, the last insertion of the notice appeared on July 28, 1881, and no other reference was made of him. Nothing more is known of him, and his name does not appear in *Polk's Medical Directory* of 1886.

Dr. George Henry Mesker§ practiced in Chokio about a year, from shortly after his internship in the Minneapolis General Hospital in 1896 until 1897 when he moved to Olivia, Renville County.

He was born on July 10, 1873, in the township of Kelso, Sibley County, and received his preliminary education in Henderson. He studied medicine at the University of Minnesota, graduating in 1896. He did not stay long enough in Stevens County to become well known. In Olivia he practiced for over fifty years and became one of the best known physicians of Renville County. Dr. Mesker was a very civic-minded citizen; he was on the school board for thirty-three years, on the village council several years, and at one time was mayor of Olivia. For ten years he was a board member and president of the Riverside Sanatorium committee.

In 1943 he joined the Army Medical Corps and was stationed in Savage, Minnesota, in Pueblo, Colorado, and St. Louis, Missouri. He returned to Minnesota in 1945 and, after working as a psychiatrist at the Cambridge State Hospital, he located again in Olivia.

He was one of the organizers of the Camp Release District Medical Society, a charter member of the Renville County Medical Society, and the first president of the Renville-Redwood Medical Society. He was a member of the Minnesota State Medical Association and its "50 Club," and the American Medical Association.

Dr. Mesker reaped many honors: a plaque for his service on the school board, a citation for his work in behalf of the Riverside Sanatorium, and he was one of the two physicians honored at the fifty-fourth annual Old Settlers reunion in 1955.* He died on November 19, 1956, from cardiovascular disease.

**Dr. G. M. Lambert went to Stillwater in 1861 ("Medicine in Washington and Chisago Counties," MINNESOTA MEDICINE, July 1938, p. 506).

†According to the same medical history (p. 568) a Dr. George A. Lambert came to Stillwater in 1872. This probably refers to the same man.

‡The State Historical Society of Kansas was unable to trace Laurel in that state.

§Obituary in MINNESOTA MEDICINE, January, 1957, and *Olivia Times-Journal,* November 22, 1956.

**Olivia Times-Journal,* June 30, 1955.

Dr. G. Olsen's professional card appeared in a Morris newspaper of August 3, 1879, "G. Olsen, late of Germany, physician and surgeon. Office at Helgeson and Hanson's Store, Morris, Minn." The same paper announces that Dr. G. Olsen had arrived in Morris and guarantees a cure or no pay. Nothing more is known of him.

Dr. Arthur R. Pollock, a graduate of the medical department of Washington University (St. Louis Medical College) St. Louis, in 1898, was licensed on June 16 of that year and recorded his license in Stevens County in the following month. He located in Chokio, which at that time was a village of 200 people. He was elected president of the Chokio Board of Health and he was examiner for the New York Life Insurance Company, the Northwest Mutual and other insurance companies. In March, 1900, he moved to Graceville, Big Stone County, where he took over Dr. R. D. Alway's practice. He is listed in Graceville through 1905, though according to other information, he is listed in Antonio, Conejos County, Colorado, in 1904 and 1906. In 1908 and 1909 he was in Ely, Pine County, Nevada.

Dr. William Davidson Rea had a big "write-up" in the *Morris Tribune* of January 5, 1901. "An audience of men and women, 600 of them, listened to a medical address given by Dr. Rea. His greatest success and the rapidity of his cures are a revelation to the special practice of medicine. His office is daily thronged with patients from all parts of the state . . ." and he continues in the same vein of a typical quack. He claims to have taken special courses besides the regular ones and to have a system with which he cures the most obstinate chronic diseases. He has studied "in the principal hospitals of Europe and America." He started early to devote himself to medicine; coming "from a stock of long-lived physicians, he inherited to a degree certain instincts . . ." and it continues *ad nauseum.* "Dr. Rea will continue to visit professionally the principal cities of the Northwest every four weeks as usual. Morris, Morris Hotel." —January 31, 1901.

He was born in Milton, Kentucky, in 1864, and graduated from the Hospital College, Louisville, Central University in 1888. In 1898 he was in Minneapolis, but soon moved to New Ulm, Brown County. From about 1903 to 1909 he was again in Minneapolis and then practiced as an itinerant physician in various parts of Minnesota and in a number of other states. He was licensed in Minnesota by examination in June, 1898, but later secured licenses in South Dakota, Missouri, Illinois, Texas and Georgia. Finally, in 1936, his Minnesota license was revoked because of "grossly improbable statements."

(To be concluded in the April issue)

Underweight Children Gain and Retain Weight with Nilevar®

One of the most convincing evidences of the anabolic activity of Nilevar, brand of norethandrolone, has been its ability to improve appetite and increase weight in poorly nourished, underweight children.

A highly important feature of the weight gain thus produced is that it is not ordinarily manifested by deposition of fat but as muscle tissue resulting from the protein anabolism induced by Nilevar.

Anorexia and "Weight Lag" Study—Brown, Libo and Nussbaum have reported* consistent and definite increases in rate of weight gain in eighty-six patients, ranging in age from 7 weeks to 15½ years. This beneficial action of Nilevar was observed in the patients with organic and traumatic disorders as well as those whose only complaints were poor appetite and/or persistent failure to gain weight.

In this study, the weight gained was not lost after discontinuance of Nilevar therapy although many patients did not continue the sharp gains effected by the drug.

The authors are of the opinion that Nilevar is a highly useful anabolic agent for influencing weight gain in underweight children.

When Nilevar is administered to children a dose of 0.25 mg. per pound of body weight is recommended and continuous dosage for more than three months is not recommended.

Nilevar is supplied as tablets of 10 mg., drops of 0.25 mg. per drop and ampuls of 25 mg. in 1 cc. of sesame oil. Further dosage information in Searle Reference Manual No. 4.

New York University Course

(Continued from Page 78)

The lectures summarize the latest concepts of the physiology of the heart, vascular circuits, the kidneys, the lungs, the liver, endocrine glands and the body fluids.

Particular emphasis is placed on principles of metabolism including body fluid and electrolyte metabolism. Fluid and electrolyte problems and metabolic disturbances are investigated as consequences of primary disorders with a view to individualized appropriate treatment. Under the direction of Dr. Norman Deane.

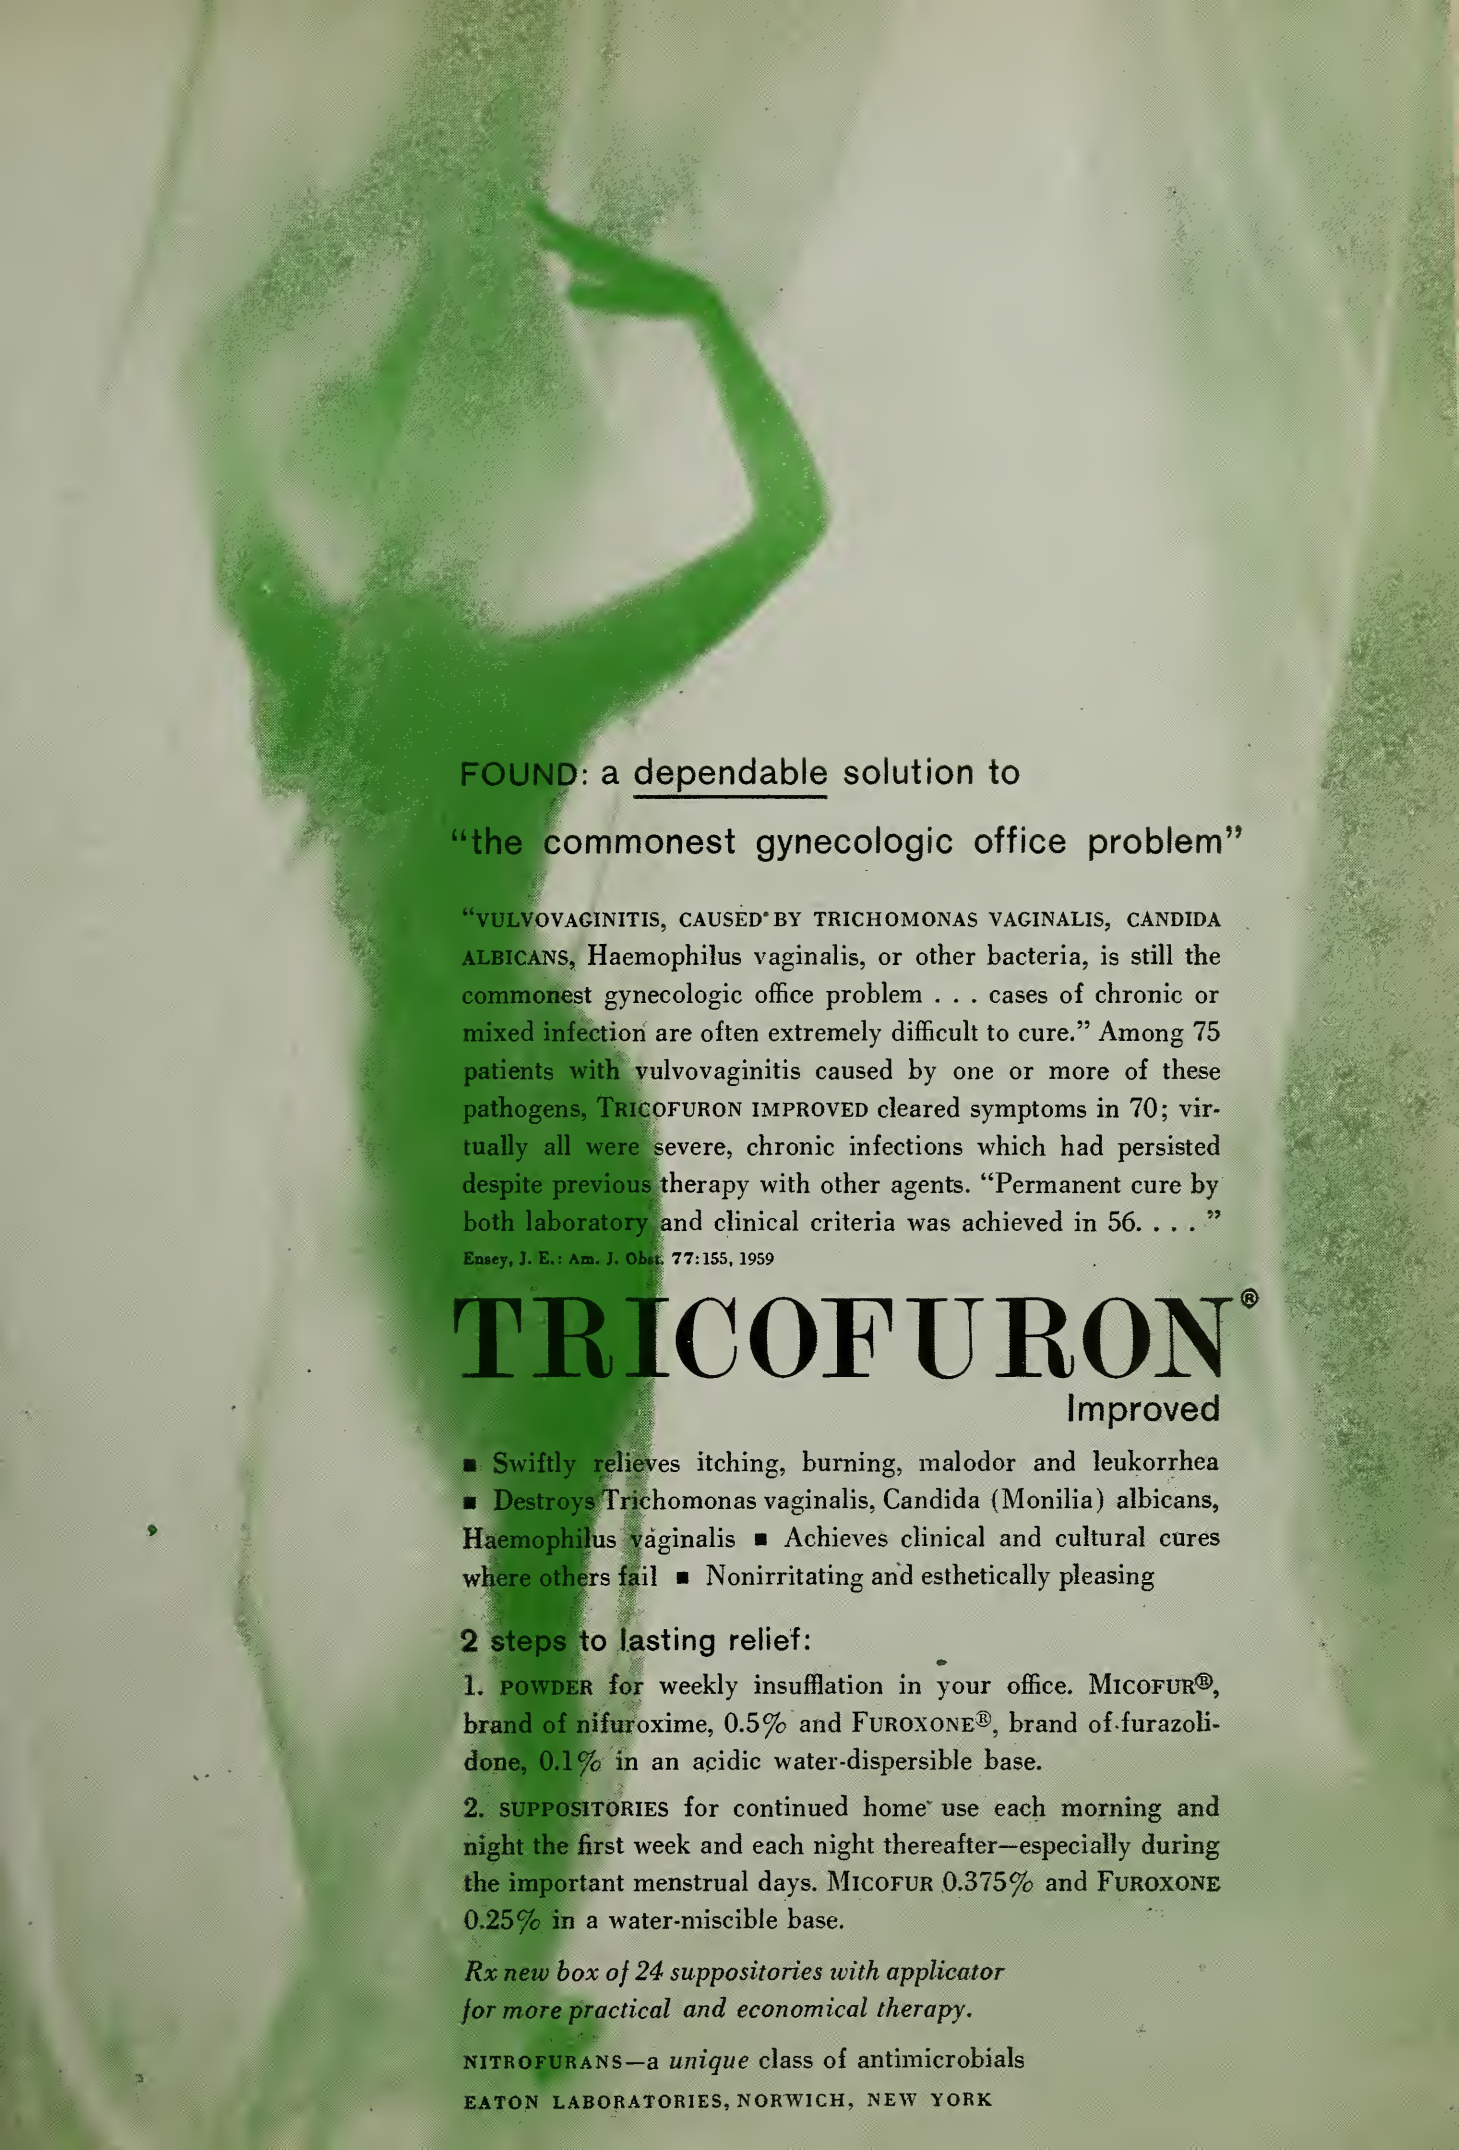
PROFESSIONAL NURSE TRAINEESHIP PROGRAM ANNOUNCED

Two new publications on the Professional Nurse Traineeship Program have been announced by Mrs. Apollonia O. Adams, Chief, Division of Nursing Resources, Public Health Service. Under the single title "Professional Nurse Traineeships," the publications are: Part I—A Report of the National Conference to Evaluate Two Years of Training Grants for Professional Nurses, and Part II—Facts About the Nurse Supply and Educational Needs of Nurses.

The Evaluation Conference report contains the major recommendations made by the sixty-eight conferees who met in Washington, D. C., August, 1958, to study the effectiveness of the traineeship program in meeting the needs for nurse administrators, supervisors and teachers. It is also an analysis of the first attempt of this kind by the Federal government to close the gap between the supply and demand for key nursing personnel.

Part II is a revision and up-dating of the source material provided to the conferees. Included is complete information on the nurses who received this aid during the first two years, statistics and graphics on the need for nursing personnel in hospitals, schools of nursing, health agencies, and nursing homes. Much of this material had never been collected before.



Both publications are available from the Superintendent of Documents, U. S. Government Printing Office, Washington 25, D. C. Part I is thirty cents; Part II is twenty-five cents.

ABC RADIO BEGINS NEW FAMILY HEALTH SERIES

A Minnesota physician has been scheduled to appear on one program of a new thirteen-week series of ABC network broadcasts dealing with common illnesses that

(Continued on Page A-68)

FOUND: a dependable solution to "the commonest gynecologic office problem"

"VULVOVAGINITIS, CAUSED BY TRICHOMONAS VAGINALIS, CANDIDA ALBICANS, Haemophilus vaginalis, or other bacteria, is still the commonest gynecologic office problem . . . cases of chronic or mixed infection are often extremely difficult to cure." Among 75 patients with vulvovaginitis caused by one or more of these pathogens, TRICOFURON IMPROVED cleared symptoms in 70; virtually all were severe, chronic infections which had persisted despite previous therapy with other agents. "Permanent cure by both laboratory and clinical criteria was achieved in 56. . . . "

Ensey, J. E.: Am. J. Obst. 77:155, 1959

TRICOFURON®

Improved

■ Swiftly relieves itching, burning, malodor and leukorrhea ■ Destroys Trichomonas vaginalis, Candida (Monilia) albicans, Haemophilus vaginalis ■ Achieves clinical and cultural cures where others fail ■ Nonirritating and esthetically pleasing

2 steps to lasting relief:

1. POWDER for weekly insufflation in your office. MICOFUR®, brand of nifuroxime, 0.5% and FUROXONE®, brand of furazolidone, 0.1% in an acidic water-dispersible base.

2. SUPPOSITORIES for continued home use each morning and night the first week and each night thereafter—especially during the important menstrual days. MICOFUR 0.375% and FUROXONE 0.25% in a water-miscible base.

Rx new box of 24 suppositories with applicator for more practical and economical therapy.

NITROFURANS—a *unique* class of antimicrobials

ABC RADIO BEGINS NEW FAMILY HEALTH SERIES

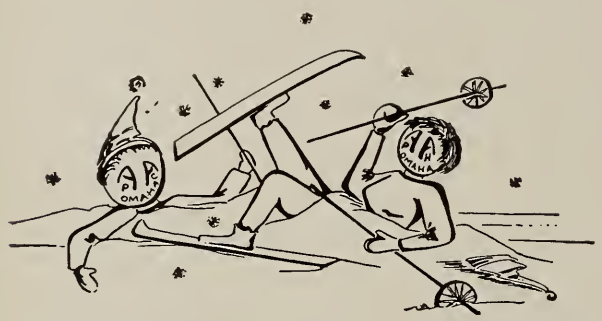
(Continued from Page A-66)

strike American families, and their treatment by family physicians.

Dr. Paul J. Bilka, Minneapolis internist, will appear on one of the fifteen-minute weekly programs devoted to arthritis.

The new public service radio series began the first week in December over the nationwide network of the American Broadcasting Company.

The series is under the supervision of the American Medical Association and is called "Highroad to Health." It is being presented in cooperation with Lederle Laboratories, a Division of American Cyanamid Company.



Weekly programs of fifteen minutes each deal with a wide range of health problems from the careless household accident to the burdens created by chronic illness. Subjects to be covered include hypertension, acute childhood infections, cancer, household accidents, toxemia of pregnancy, chronic illnesss, geriatrics, mental health, rheumatic fever, tetanus, surgery, nutrition and medical emergencies.

Each program opens with a nine-minute dramatization of a health problem. This is followed by a five-minute discussion of the problem by a guest physician who also answers questions posed by the program host.

Dr. Gerald Dorman, Eastern Co-Chairman of the Physicians' Advisory Committee on Radio and Television of the AMA, has said of the series, "We feel that 'Highroad to Health' will be a useful link between the public and the medical profession. It will cover a wide range of health problems in a factual, informative answer and will contribute to a better understanding of how the family physician wants to guard family health."

"Highroad to Health" is available to ABC stations each Wednesday at 2:15 P.M. and also each Saturday at 10:30 A.M. Local newspaper program listings or ABC stations should be consulted for exact broadcast schedules.

Minnesota ABC stations are: KATE, Albert Lea; KXRA, Alexandria; KTOE, Mankato; KDMA, Montevideo; WTCN, Minneapolis-St. Paul; KWLM, Willmar; KWNO, Winona; and KMHL, Marshall.

SOCIETY FOR ADVANCEMENT OF HYPNOSIS ORGANIZED

A group of physicians and dentists in the Twin Cities, who are presently using hypnosis in their practice, are forming a local society devoted to the advancement of hypnosis in medical and dental practice. Physicians or dentists interested in joining the society are asked to contact Frank J. Bonello, M.D., 711 So. Smith Ave., St. Paul 7, Minn. CA. 7-7056.

CHICAGO OPHTHALMOLOGICAL SOCIETY CONFERENCE

The Chicago Ophthalmological Society will hold its annual clinical conference, February 12 and 13, 1960, at the Drake Hotel, Chicago, Illinois.

Guest speakers will include Dr. Walter S. Atkinson, Watertown, N. Y., Dr. Gilbert Baum, Port Chester N. Y., Dr. James Bennett, Cleveland, Ohio, Dr. Paul Cibis, St. Louis, Mo., Dr. Robert Hollenhorst, Rochester, Minn., Dr. Bertha A. Klien, Chicago, Ill., Dr. Peter C. Kronfeld, Chicago, Ill., Dr. Oscar Sugar, Chicago, Ill., Dr. Isaac Tassman, Philadelphia, Pa., and Dr. Derrick T. Vail, Chicago, Ill.

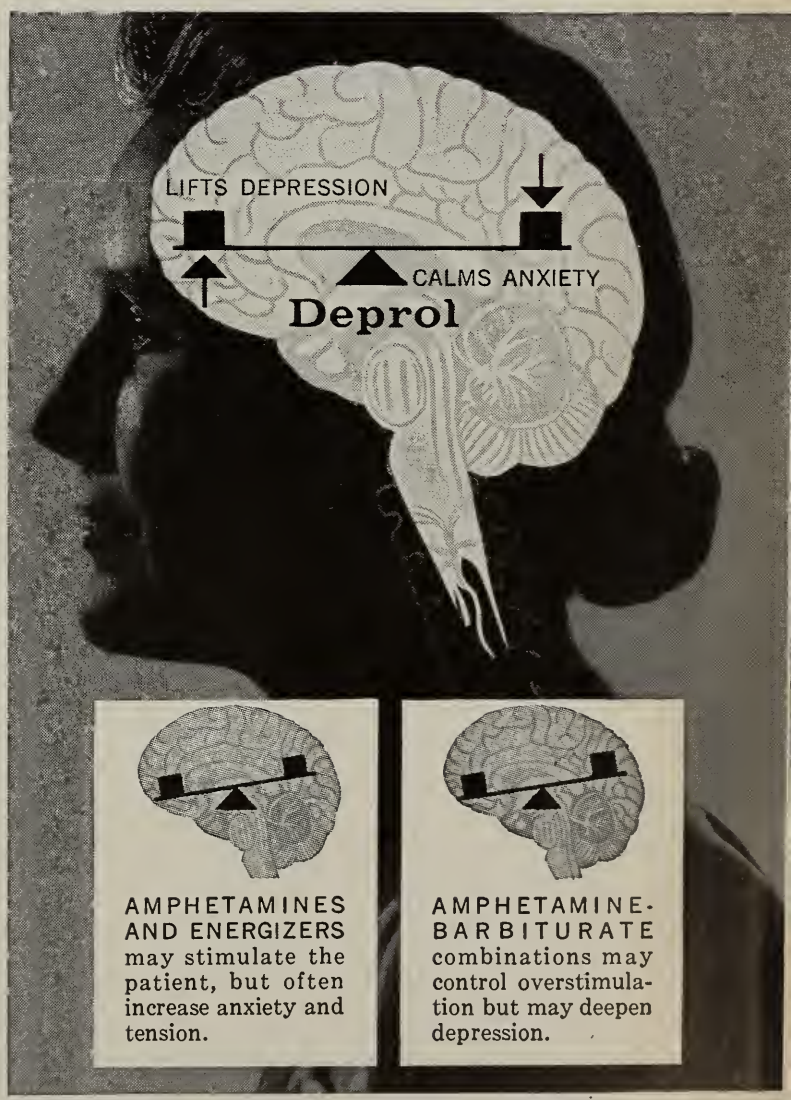
The subjects will include a symposium on retinal disorders, ophthalmo-dynamometry in intracranial vascular disease, observation on cataract surgery, ultrasonography in clinical ophthalmology, photocoagulation of iris and retina, a new surgical approach to lacrimation problems, a neurosurgeon looks at ophthalmology, ligament of Wieger.

Registration fee for the entire course including round table luncheons and dinner following the Gifford Memorial Lecture is $45.00 and may be payable to the Registrar: Mrs. Edward J. Ryan, 1150 North Lorel Avenue, Chicago 51, Illinois.

The sixteenth annual Sanford R. Gifford Memorial Lecture will be delivered by Dr. Walter S. Atkinson of Watertown, New York, on Friday, February 12, 1960, at the Drake Hotel at 5:15 p.m. All ophthalmologists are invited to attend the Gifford Memorial Lecture and the dinner which follows.

as it calms anxiety!

Deprol helps balance the mood by lifting depression as it calms related anxiety



No "seesaw" effect of amphetamine-barbiturates and energizers

While amphetamines and energizers may stimulate the patient—*they often aggravate anxiety and tension.* And although amphetamine-barbiturate combinations may counteract excessive stimulation—*they often deepen depression.*

In contrast to such "seesaw" effects, Deprol lifts depression as it calms anxiety—both at the same time.

Safer choice of medication than untested drugs

Deprol does not produce hypotension, liver damage, psychotic reactions or changes in sexual function.

MINNESOTA HEART ASSOCIATION AND FEDERATED FUNDS

The Minnesota Heart Association always welcomes the careful and critical scrutiny of responsible citizens concerned with the multiplicity of health drives. Our affairs and records are public property, and the expenditure of Heart Fund dollars is prudently directed by unpaid volunteers who serve thousands of hours each year to see that the best results are obtained from each contribution made.

We accept completely the results of the Twin Cities survey carried out by Mid-Continent Surveys, and have no question about its authenticity, accuracy, or integrity. However, we do feel that the depth and scope of the study might have been greater because in our opinion the one crucial question was not asked or answered.

This question is: How can the Minnesota Heart Association, or any other major health agency dealing with a significant health problem, be expected to carry out the public's wishes if such agencies must be included in a federated fund campaign which cuts income at least in half and markedly diminishes the public information phases? The public is asking the Minnesota Heart Association to assume more and more responsibility in the field of heart disease control; physicians are being asked more and more by thoughtful patients when this problem of heart disease will be solved; and in conclusion it appears to us that the public is simply supporting its own interests when it chooses to contribute to the independent Heart Fund. These contributions are not being made to an outside agency, for the Minnesota Heart Association belongs to and is responsible to the public. Contributions are personal investments of individuals who are seeking answers to the baffling questions of heart disease.

It is good to know from the Mid-Continent survey that under our democratic free-choice system 73 per cent of those rendering an opinion said they wished to designate where their gifts are to go. Our country handles in a voluntary fashion many of its problems that other countries solve through government, and this local reflection of our desire to spend our money so it goes to the causes of our own choice represents again a desirable facet of American life, a facet, I am sure, most of us cherish dearly.

The sole purpose of the Minnesota Heart Association is to reduce the appalling toll of death and disability caused by diseases of the heart and blood vessels. We have but one state-wide organization with no formal chapters or affiliates on the local level; we believe this arrangement results in a wiser use of funds raised, a more economical use of limited resources, and reduces our costs of fund raising and administration. Heart disease is this country's number one cause of death, and in fact more Minnesotans die from heart disease than from all other causes combined. Under these circumstances, no thoughtful person can conscientiously lump together the problem of heart disease with the over all multitude of other drives of more limited scope, no matter how worthy they may be.

Placing the Minnesota Heart Association and its research, education, and community service programs within the framework of a Community Chest, United Fund, or other similar federated fund-raising scheme does a distinct disservice to the thousands of volunteers who work faithfully to raise funds. This approach simply postpones the day when eventual scientific break-throughs will come. Our battle is against heart disease; and we know our cause will move ahead more surely and soundly when citizens are free to support the independent Heart Fund as they wish.

This Section is for you to voice your convictions, comments, and queries on all subjects political, economic, historic, humorous, scientific or otherwise, to many physicians. Writings not sufficiently formal and too brief for an editorial or a scientific manuscript are requested. Clinical and research observations, no matter how brief, similar to those in *The Lancet* (London), are particularly encouraged.

Our experience over several years in Minnesota as a part of Community Chests and United Funds shows without question that our rate of economic growth is far less in federated fund areas than in those areas where contributions are limited only by the generosity of the individual contributor. This situation is not unique to Minnesota because our experience was similar to many other heart associations throughout the country who reported equally unsuccessful participation in Community Chests and United Funds. They too stated that their fund raising remained static while they were a part of federated fund raising, and they too said that their volunteers did not maintain a sense of mission and vigor while part of a federated drive. These experiences directly parallel those of the Minnesota Heart Association. Other heart affiliates also agree that funds available for research to solve the problem of heart disease were materially reduced by such participation. Therefore, in May, 1957, independent of any policy of our parent group, the American Heart Association, our board of directors unanimously voted to end all further participation in federated fund raising. In fact, our association was the first to withdraw on a state-wide basis, and this precedes the present American Heart Association policy in this respect. This decision was reached only after long and mature consideration. Growth of the Heart Fund since this withdrawal has definitely substantiated this action.

Recognizing the importance of this step, our board of directors reviewed the withdrawal policy one year later, and again come to the same conclusion. The decision of the Minnesota Heart Association was made solely upon its own experiences in this state and was in no way influenced or directed by any outside group.

We will continue to rest our case with the contributing public, for under our present policies we cannot participate in any Community Chest or United Fund. We must therefore at the present time decline any invitation, no matter how well intentioned, to be a part of any federated fund campaign anywhere in the state of Minnesota; but this does not mean that we feel other health agencies primarily oriented to direct service programs would not be wise to consider such affiliation with a United Fund.

We are very pleased, however, to be a part of the in-plant employe solicitation in many hundreds of fine Minnesota firms. This is called a "United Appeal" and must be clearly distinguished from "United Fund" which is a community-wide federated drive. We participate when the United Appeal is conducted under the following conditions: (a) they are entirely voluntary; (b) the agencies are listed separately so that the giver may exercise his or her option to designate the recipient of his or her gift; (c) the right of the employe to give or not to give is maintained, and (d) if adequate and

(Continued on Page A-80)

A single 5 mg. tablet once a day provides all these advantages[2]

- prolonged action — in excess of 18 hours
- convenient once-a-day dosage
- low daily dosage — more economical for the patient
- no significant alteration in normal electrolyte excretion pattern
- repetitively effective as a diuretic and antihypertensive
- greater potency mg. for mg.—more than 100 times as potent as chlorothiazide
- potency maintained with continued administration
- low toxicity — few side effects — low salt diets not necessary
- comparative studies with chlorothiazide, hydrochlorothiazide, and Naturetin disclose that smallest doses of Naturetin produce greater weight loss per day
- in hypertension, Naturetin, alone or in combination with other antihypertensives, produces significant decreases in mean blood pressure and other favorable clinical effects
- purpura and agranulocytosis not observed
- allergic reactions rarely observed

[2]Reports (1959) to the Squibb Institute for Medical Research.

Naturētin —*Indications:* in control of edema when diuresis is required, in congestive heart failure, in the premenstrual syndrome, nephrosis and nephritis, cirrhosis with ascites, edema induced by drugs (certain steroids); in the management of hypertension, used alone, combined with Raudixin (Squibb Rauwolfia Serpentina Whole Root), or with other antihypertensive drugs, such as ganglionic blocking agents.

Contraindications: none, except in complete renal shutdown.

Precautions: when Naturetin is added to an antihypertensive regimen including hydralazine, veratrum, and/or ganglionic blocking agents, immediate reduction must be made in the dosage for all preparations; the dosage for ganglionic blocking agents must be decreased by 50% to avoid a precipitous drop in blood pressure. This also applies if these hypotensive drugs are added to an established Naturetin regimen . . . in hypochloremic alkalosis with or without hypokalemia . . . in cirrhotic patients or those on digitalis therapy when reductions in serum potassium are noted . . . in diabetic patients or those predisposed to diabetes . . . when increased uric acid concentrations are noted . . . when signs—leg or abdominal cramps, pruritus, paresthesia, rash—suggestive of hypersensitivity, are noted.

Naturētin —*Dosage: in edema,* average dose, 5 mg., once daily, preferably in the morning; to initiate therapy, up to 20 mg., once daily or in divided doses; for maintenance, 2.5 to 5.0 mg., daily in a single dose. *In hypertension:* suggested initial dose, 5 to 20 mg. daily; for maintenance, 2.5 to 15 mg. daily, depending on the individual response of the patient. When Naturetin is added to an antihypertensive regimen with other agents, lower maintenance doses of each drug should be used.

Naturētin —*Supplied:* tablets of 2.5 mg. and 5 mg. (scored).

MINNESOTA HEART ASSOCIATION

(Continued from Page A-76)

reasonable provision is made for the conduct of educational programs by the Heart Association.

The public knows our association's principal objective is the support of long-term research into the causes and cures of heart disease; it knows of our extensive professional and public education programs; it knows of our expanding community service activities; and we rest our case, as ultimately every group must do under our democratic system, in the hands of the individual. We are confident that the citizens of Ramsey and Hennepin counties, and other counties throughout our state, will continue to support our work generously because they know of our program and our needs.

It is our sincere hope that this public discussion of the merits of federated fund raising versus independent fund raising will not create such differences of opinions that the total level of giving in our communities will decline. We are fully aware of the importance of proper support for purely local needs and in fact many of our most dedicated volunteers have been and will continue to be devoted supporters and solicitors for these very worthy causes. However, the Minnesota Heart Association will not evade its responsibility to the thousands of Minnesotans who are today afflicted with heart disease, nor will we contribute to any unwarranted delay in accomplishing our objective of an early victory over heart disease by participating in federated fund raising. Time is indeed running out for thousands of our friends and relatives who face an untimely end from heart disease.

Richard J. Rothmund

COMMUNITY CANCER DEMONSTRATION PROJECTS

Nine grants totaling $321,894 have been awarded by the Public Health Service to support Community Cancer Demonstration Projects.

Ranging in location from Hawaii to Puerto Rico, the nine projects were recommended for approval by the Advisory Committee to the Cancer Control Program, and the National Advisory Cancer Council. Five of the projects will deal with tumor records and registries, two will screen large numbers of women for cancer of the cervix, and two will further education in cytology, the science of cells.

Purpose of the studies financed by the grants is to shorten the interval between discoveries in research and the application of these findings at the community level, the Surgeon General said. They are the first to be assigned from the $1,500,000 appropriated by Congress for this purpose during the current fiscal year.

The Cancer Control Program, within the Division of Special Health Services, Public Health Service, is administering the fund, and is receiving applications from health agencies and nonprofit organizations and institutions. Additional projects will be approved next spring and summer.

Among the specific opportunities believed to exist for the prevention and control of cancer are professional and technical education in cytology, screening women for cervical cancer, the importance of including cancer diagnostic aids in complete health examinations, evaluation of public educational activities, tumor registries collecting data of exceptional value, and selected therapeutic and rehabilitative programs.

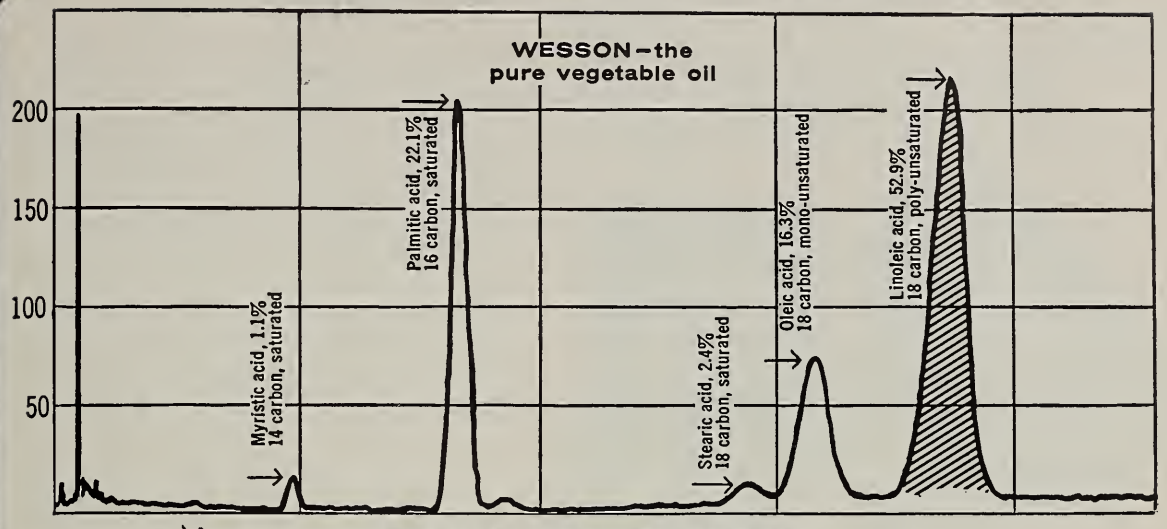
Annual Clinical Conference

CHICAGO MEDICAL SOCIETY

March 1, 2, 3 and 4, 1960

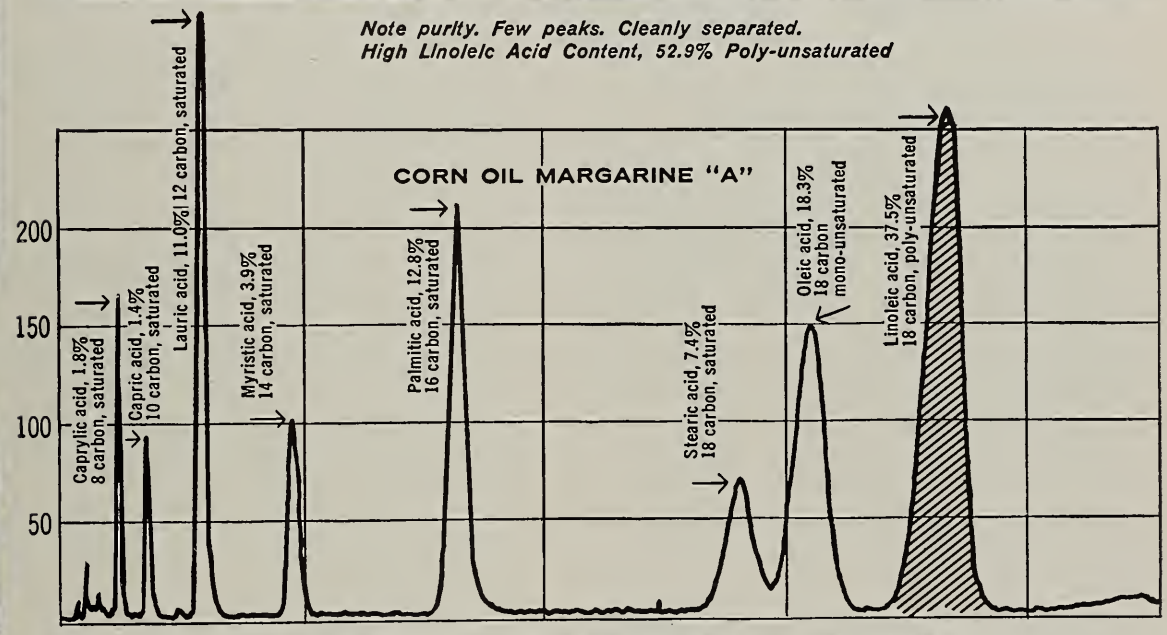
Palmer House, Chicago

Daily Half-Hour Lectures by Outstanding Teachers and Speakers on subjects of interest to both general practitioner and specialist.



Panels on Timely Topics — **Teaching Demonstrations**

Medical Color Telecasts — **Instructional Courses**



Scientific Exhibits worthy of real study and helpful and time-saving Technical Exhibits.

The Chicago Medical Society Annual Clinical Conference should be a MUST on the calendar of every physician. Plan now to attend and make your reservations at the Palmer House.

In Memoriam

OSCAR DAIGNAULT

Dr. Oscar Daignault, physician and surgeon in Benson, Minnesota, from 1900 to 1948, died November 18. 1959. The deceased was eighty-four years old at the time of his death. He had retired from active practice in May, 1948, due to failing health.

Doctor Daignault was born in Montreal. Canada. where he also received his preliminary education. He obtained his medical education at the University of Montreal Medical School, a branch of Laval University. Following graduation he practiced for a short time in Saint Paul before moving to Benson.

The deceased was a member of the Kandiyohi-Swift-Meeker County Medical Society and the American Medical Association. He was a life member of the Minnesota State Medical Association.

Survivors include his wife, Grace; one son, Rene, of California, and three sisters, Mrs. Alice Laperrie, Mrs. Lydia DeMarce, and Georgette Daignault, all of Montreal, Canada.

JOHN E. HYNES

Doctor John E. Hynes, who practiced medicine at S.E. Bedford and University Avenues, Minneapolis. for more than fifty-four years, died December 9, 1959, at the age of eighty-one.

The deceased was born in Winnebago, Minnesota, and received his preliminary education in the public schools of that community. His medical education was obtained at the University of Minnesota. He served on the staff of Saint Mary's Hospital, Minneapolis, and was chief of staff of that hospital.

Doctor Hynes was a member of the Hennepin County Medical Society and a life member of the Minnesota State Medical Association.

In addition, he was a member of the Minnesota Academy of Medicine in which he had been president and secretary-treasurer, and he was active in the Republican Party politics.

Survivors include a daughter, Mrs. Franklin G. Wallace, Mound; a son, Doctor John E. Hynes, Jr., Billings, Montana, and a brother Joseph, Winnebago, Minnesota.

MELVIN S. NELSON

Dr. Melvin S. Nelson, Granite Falls physician, died November 10, 1959, at the age of seventy-six years.

The deceased was prominent in community affairs of Granite Falls during the major portion of his life. He served as an active member of the Granite Falls School Board and was a past president of the Granite Falls Golf Club for a number of years.

Doctor and Mrs. Nelson established the first Granite Falls Hospital shortly after their arrival in that community. When Granite Falls built the present hospital, Doctor and Mrs. Nelson donated their own hospital building and property and equipment to the Granite Falls community as a gift.

Doctor Nelson was born in Appleton, Minnesota. He received his medical education at the University of Minnesota Medical School. Before his practice in Granite Falls, Doctor Nelson practiced from 1909 to 1914 in Mora, Minnesota, and from 1914 to 1924 in Spring Grove, Minnesota.

Some of the positions held by Doctor Nelson include membership of the Mora hospital staff, membership of the Spring Grove hospital staff and membership of the Granite Falls hospital staff. He was also affiliated with the United States Army Debarcation Hospital in New York for one year.

Doctor Nelson was granted life membership in the Minnesota State Medical Association in 1959, and he was a member of the Camp Release Medical Society and the American Medical Association.

ROBERT I. RIZER

Dr. Robert I. Rizer, Minneapolis internist, died November 13, 1959, at seventy-six years of age.

The deceased began his practice of Internal Medicine in 1915 in Minneapolis and retired in 1956.

A native of Boone, Iowa, Doctor Rizer graduated from the University of Chicago and Rush Medical School, Chicago. Before coming to Minneapolis, he studied in Vienna.

After graduation, he practiced medicine for three years in Anaconda, Montana, from 1910 to 1913.

He was on the staff of Northwestern Hospital and was a clinical associate professor of internal medicine at the University of Minnesota.

Doctor Rizer was a member of the American Board of Internal Medicine, the Minneapolis and Minnesota societies of Internal Medicine, the Minneapolis Club and Nu Sigma Nu professional fraternity.

In 1955, Doctor Rizer was granted life membership in the Minnesota State Medical Association. He was also a member of the Hennepin County Medical Society and the American Medical Association.

Survivors include his wife, Grace R.; two daughters, Mrs. Frederick Paffard, Sewickley, Pennsylvania, and Mrs. Howard Rue, Philadelphia, Pennsylvania; and two sons, Dr. Dean K., Wayzata, and Robert I., Jr., of Mound.

The Physician's Diary

Dr. Robert B. Howard, Dean of the Medical School, University of Minnesota, and **Dr. Richard Magraw,** Assistant Dean, were guest speakers at the recent meeting of the Brown County Medical Association. Auxiliary members were entertained at the home of **Dr.** and Mrs. **E. L. Penk,** Springfield.

* * *

The Board of Governors of the Mayo Clinic has confirmed the election of **Dr. O. H. Beahrs** to fill the unexpired term of **Dr. Waltman Walters,** who retired from the Board.

* * *

Members of the Southwestern Minnesota Medical Society heard the purposes and objectives of the new three-county Mental Health Clinic at Worthington recently. Guest speakers at the meeting were a clinical psychologist and a psychiatric social worker from Luverne. Auxiliary guests were entertained at the home of **Dr.** and Mrs. **John Lohmann,** Worthington.

* * *

The new members of the Mayo Clinic staff include the following: **Dr. J. T. Martin,** consultant in section of anesthesiology; **Dr. C. G. Moertel,** consultant in section of medicine; **Dr. P. J. Osmundson,** consultant in section of medicine; **Dr. C. A. Pascuzzi,** consultant in section of clinical pathology; **Dr. L. F. A. Peterson,** consultant in section of orthopedic surgery; **Dr. G. E. Plum,** consultant in section of diagnostic roentgenology; **Dr. Alexander Schirger,** consultant in section of medicine; **Dr. R. E. Smith,** consultant in section of medicine; **Dr. R. J. Spencer,** consultant in section of proctology; **Dr. R. M. Steinhilber,** consultant in section of psychiatry; **Dr. W. N. Tauxe,** consultant in section of clinical pathology; and **Dr. J. W. Worthington, Jr.,** consultant in section of medicine.

* * *

Dr. Dale C. Cameron, State Medical Director, has announced his resignation from that post effective January 31. Doctor Cameron plans to accept a position with the Federal Public Health Service. A successor to Doctor Cameron has not yet been named. Members of the Mental Health Policy Committee which will aid in the selection of a successor include **Dr. Bernard C. Glueck, Jr.,** University of Minnesota; **Dr. Samuel Boyer,** Duluth, and **Dr. John Anderson,** University of Minnesota.

* * *

Retiring members of the Mayo Clinic staff were honored at the annual meeting of that association. They include: **Dr. J. A. Bargen,** chairman of the section of gastroenterology; **Dr. J. S. Lundy,** senior consultant in and former head of the section of anesthesiology, and **Dr. Hamilton Montgomery,** senior consultant in dermatology.

* * *

Dr. Frederick C. Goetz, University of Minnesota, was chairman of a diabetes detection drive in the Twin Cities recently. **Dr. Philip Soucheray,** St. Paul, and **Dr. Moses Barron,** Minneapolis, were captains of their respective cities. The drive was aimed at alerting the public to the importance of taking a simple test for diabetes.

* * *

A former member of the Mayo Clinic staff and emeritus professor of medicine in the Mayo Foundation, Graduate School, **Dr. Walter C. Alvarez** was given an award recently by the New York City Chapter of the American Medical Writers' Association for distinguished service in the improvement of medical communication. Ceremonies took place at the New York University School of Dentistry in Manhattan.

* * *

Dr. M. H. Larson, who maintained a medical practice in Lake Benton for the past six and one-half years, recently resigned that position and accepted a position on the staff of the Minnesota State Hospital at St. Peter.

* * *

Among members of the Mayo Clinic staff who attended recent medical meetings were: **Drs. R. W. P. Achor, E. D. Bayrd, K. G. Berge, J. L. Juergens, H. R. Butt, H. M. Carryer, D. C. Connolly, M. B. Divertie, W. T. Foulk, E. E. Gambill, G. A. Hallenbeck, N. G. Hepper, J. A. Higgins, K. A. Huizenga, F. T. Maher, R. D. Miller, D. R. Nichols, C. A. Owen, T. W. Parkin, H. F. Polley, W. G. Sauer, H. H. Scudamore, C. H. Scheifley, R. E. Smith, M. H. Stauffer, L. E. Ward** and **C. H. Watkins.**

* * *

Dr. O. J. Seifert, New Ulm, recently announced the addition of a new physician on the Seifert Clinic staff. Starting recently was **Doctor John H. Baker,** a native of Uxbridge, Massachusetts.

* * *

Duluth physician, **Dr. William B. Martin,** recently directed a diabetes campaign in the Duluth area. **Dr. James C. Trautmann,** also of Duluth, assisted Doctor Martin in the drive.

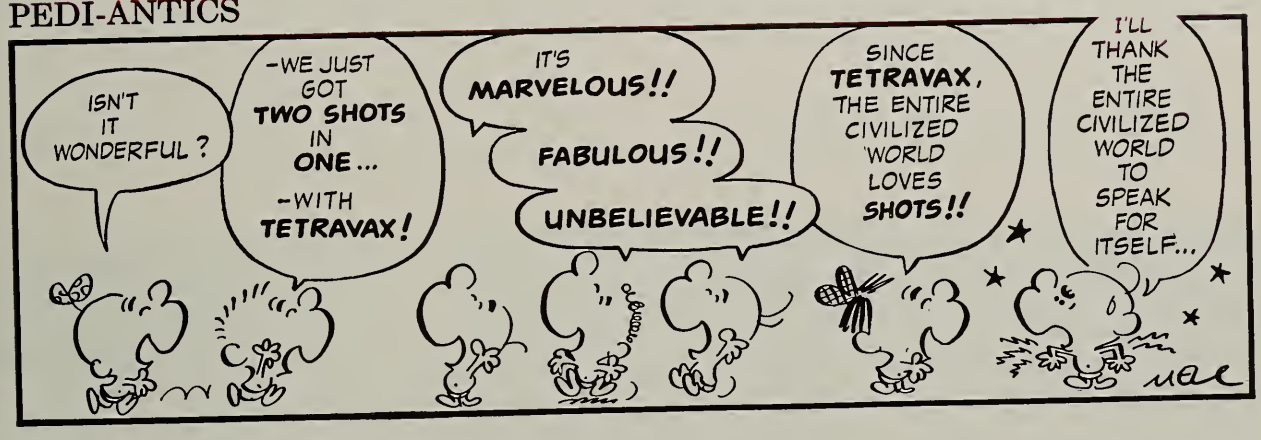
* * *

Dr. Edgar V. N. Allen, Rochester, was awarded the 1959 Gold Heart Award of the American Heart Association. Doctor Allen was one of three receiving awards for outstanding contributions to cardiovascular medicine.

* * *

A Hibbing surgeon, **Dr. L. W. Johnsrud,** was a guest speaker at a meeting of the Saturday Club of Hibbing. Doctor Johnsrud spoke on "Medical Education in the United States Today." Following his talk, Doctor Johnsrud presented a film entitled, "Hands We Trust."

* * *



The White House recently announced the appointment of **Dr. Winchell McK. Craig,** emeritus member of the Mayo Clinic Staff, as Special Assistant for health

and medical affairs to the Secretary of Health, Education and Welfare. The internationally recognized neurosurgeon will be a policy adviser to Secretary Arthur S. Flemming.

* * *

Dr. Warren E. Wilson, Northfield, recently suffered a heart attack while attending a medical meeting in Chicago. Doctor Wilson was hospitalized there at St. Luke's Presbyterian Hospital for a short while.

* * *

A medical exhibit by four members of the staff of the Mayo Clinic received the first place award at the International Medical Assembly of the Interstate Postgraduate Medical Association of North America. The award was given to the exhibit "Misleading Calcific Shadows in the Abdomen" by **Drs. L. G. Bartholomew, J. C. Cain, G. D. Davis** and **A. H. Bulbulian.**

* * *

Guest speakers for the Fall Seminar of the Range Chapter of the American Academy of General Practice included **Dr. Neil Palm,** Saint Paul, Surgeon; **Dr. Harold Ravits,** Saint Paul, Dermatologist, and **Dr. Tague Chisholm,** Minneapolis, Pediatric Surgeon.

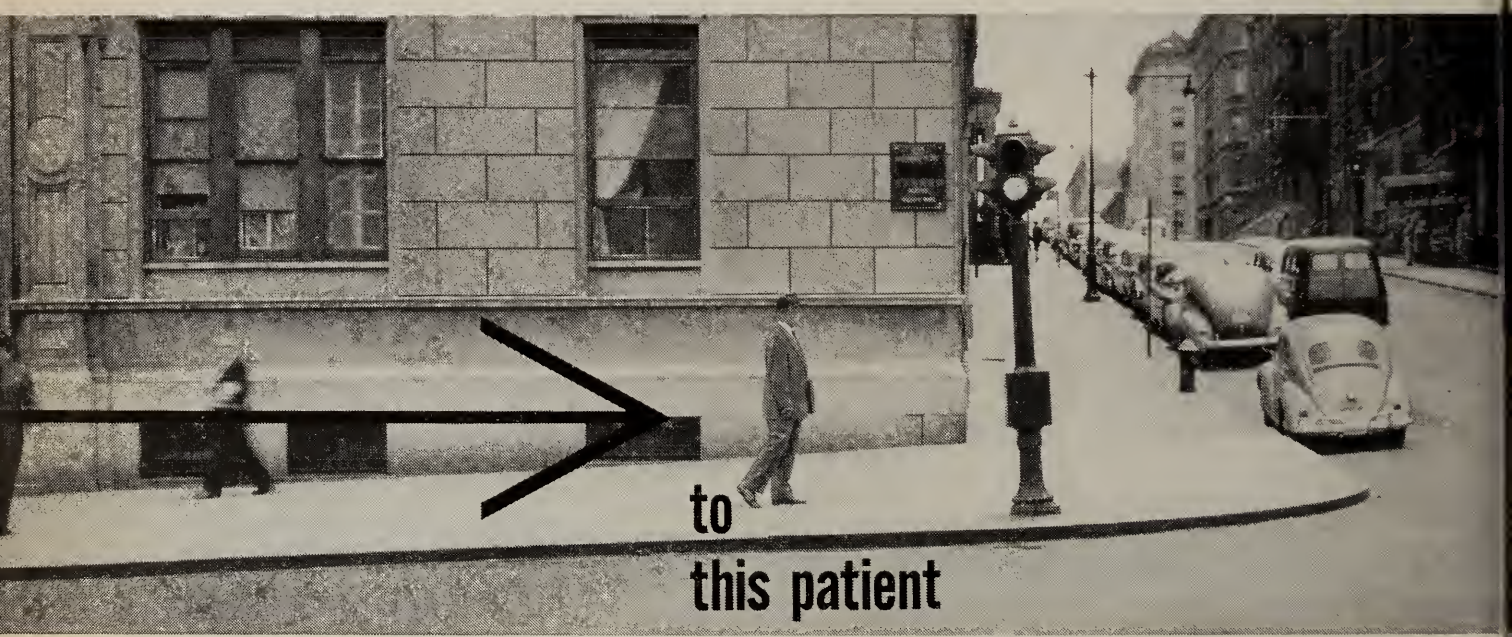
* * *

Dr. Edward A. Banner, Rochester, has been elected president of the Minnesota Obstetrical and Gynecological Society at the Society's Annual Convention. Other officers elected include **Dr. Charles McKenzie,** Minneapolis, Vice President; **Dr. Alex Barno,** Minneapolis, Secretary-Treasurer and **Dr. Jane Hodgson** to the Board of Governors.

* * *

The new office building of **Dr. John J. Smyth,** Lester Prairie, recently went into use. The building is a new block and brick structure.

* * *



The American Academy of Pediatrics recently elected **Dr. William H. Weidman,** Rochester, to membership in the specialty section on Cardiology. Doctor Weidman is a member of the postgraduate section on the heart, designed for scientific study in the practice of infants, children and adolescents.

* * *

Dr. Robert B. Howard, Dean of the University of Minnesota Medical School, had the honor of accepting a sixty-pound plaque from the National University College of Medicine in Seoul, Korea. The award was made in appreciation of work done by the staff of the University Medical School in rehabilitation of the war-torn Seoul University College of Medicine.

* * *

Dr. John Gordon, University of Minnesota, was a recent guest speaker at a meeting of the Red River Valley Medical Society held in Crookston. Doctor Gordon based his talk on problems in anesthesia.

Dr. Duane C. Olson, Gaylord, recently announced the sale of the Olson Clinic in Gaylord to **Dr. Harvey A. Knoche, Morgan.** Doctor Olson will join the medical offices of **Drs. Hagen** and **Hodges** in the Southdale Medical Center, Minneapolis.

* * *

Recipients of awards given at the thirty-fifth annual meeting of the Alumni Association of the Mayo Foundation were **Dr. Philip J. Osmundson** and **Dr. John W. Worthington,** Mayo Clinic. Doctor Osmundson received the Edward John Noble Foundation award and Doctor Worthington the Herschel V. Jones award. At the same meeting, **Dr. L. Raymond Scherer,** Minneapolis, was elected first vice president of the Association.

* * *

A recent speaker at a meeting of the American Association of University Women was **Dr. Bernard J. Spencer,** Minneapolis. Doctor Spencer spoke on "The Child and the Surgeon."

* * *

A two-day conference on Neurosurgery was held in honor of **Dr. William T. Peyton,** University of Minnesota. Doctor Peyton is Head of the University of Minnesota Division of Neurosurgery.

* * *

Dr. Robert Bloomberg, Austin, has been appointed program director of the Mower County Mental Health Clinic. Doctor Bloomberg succeeds **Dr. Carl A. Schwartz.**

* * *

The Elk River Clinic recently announced the addition of **Dr. Jo E. Anderson** to the Clinic staff.

* * *

The Duluth unit of the American Cancer Society recently elected Dr. **Philip F. Eckman,** Duluth, as president. Also elected were **Dr. Kenneth A. Storsteen,** vice president; and **Dr. Mario Fischer** to the executive committee.

* * *

Dr. George R. McNear, Jr., Mankato Clinic, has been selected to participate in the International Symposium on Scientific Medicine sponsored by the Society of Scientific Medicine of Lisbon.

* * *

It has recently been learned that **Dr. Walter A. Fansler,** emeritus clinical professor of surgery, University of Minnesota, has been appointed on the ad hoc Advisory Committee on Cancer of the Colon and Rectum of the American Cancer Society.

* * *

Dr. Katherine Nye and **Dr. Jane Hodgson,** St. Paul physicians, recently received citations for their work in the field of medicine. They were among ten St.

* * *

The Osakis Review recently announced that **Dr. E. Haberman**, of that town, was retiring. Doctor Haberman has served the town of Osakis for forty-three years in the practice of medicine.

* * *

Alexandria physician, **Dr. D. E. Perkins**, recently attended a course in clinical cardiology at the Cook County Graduate School of Medicine in Chicago.

* * *

A recent lecture marked the first use of the Kirklin-Weber Memorial Fund, honoring the memory of two former chiefs of Mayo Clinic are **Dr. Byrl R. Kirklin** and **Dr. Harry M. Weber.** The guest speaker was **Dr. Leo G. Rigler**, former Professor of Radiology at the University of Minnesota and now Executive Director of the Cedars of Lebanon Hospital, Los Angeles, California.

* * *

Announcement was made recently of the new officers of the Minneapolis Obstetrical and Gynecological Society. The elected officers are: **Dr. Maxwell Barr**, president; **Dr. George Janda**, vice president, and **Dr. Richard Fliehr**, secretary-treasurer.

* * *

The Duluth Unit of the American Cancer Society recently named **Dr. Philip F. Eckman** as president and **Dr. Kenneth E. Storsteen** as vice president.

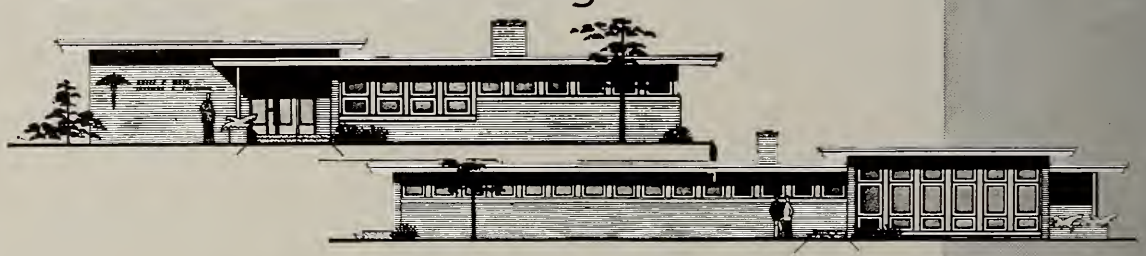
An emeritus member of the Mayo Clinic Staff, **Dr. S. W. Harrington**, recently returned from a trip to the Middle East and Europe. While abroad, Doctor Harrington attended medical meetings in Munich and Vienna, and also visited Switzerland, Yugoslavia, Greece, Turkey and the city of Jerusalem before visiting Rome.

* * *

Duluth physicians, **Dr. Andrew Reardon** and **Dr. Henry Reed**, were recently certified by the American Board of Pediatrics.

* * *

Dr. Lester N. Dale, Red Lake Falls, recently announced that **Dr. Walter E. Miller** will be associated with him in the practice of medicine for a short time.



* * *

Dr. Charles W. Mayo and **Dr. Philip Hench**, Rochester, have returned from Omaha, Nebraska, where they attended the annual presentation of the Mutual of Omaha Criss Award. Doctor Mayo is head of the award committee and Doctor Hench is a previous recipient of the award. This year's award went to **Dr. Thomas A. Dooley** of Laos.

* * *

Dr. Robert B. Howard, Dean of the University of Minnesota Medical School, was a guest speaker at a recent meeting of the Minnesota Chapter of the Arthritis and Rheumatism Foundation. Doctor Howard's talk was on "The Public's Stake in Medical Education and Research."

GENERAL INFORMATION

Authors

Manuscripts should be addressed to Arthur H. Wells, M.D., Editor, 915 East First Street, Duluth 5, Minnesota. Telephone RA 7-6636 or JA 5-2319. Original papers prepared for publication solely in Minnesota Medicine will be considered by the Board of Editors providing they fulfill the following editorial standards. Manuscripts should be typed double spaced on white paper with at least 1-inch margins. The original (not a carbon copy) is requested. The title on the first page should be under six words if possible or divided into two parts. The author should give his highest degree, his institutional position or his relationship to a hospital or medical organization which he may be addressing. Pages should be numbered consecutively and the author's last name should appear at the top of each page.

Bibliographical references should appear on a separate sheet entitled References. They should appear and be numbered consecutively in the order in which they first occur in the text (not alphabetically). Citations in the text require reference numbers if the author's or authors' names are not used or if there is more than one reference to the same author or group of authors. All references to author should appear in the list of References and no references should be included which are not in the text. The style and exact punctuation used in the J.A.M.A. references are requested. Journal references should include: *Author's last name, initial., initial.: title of paper. Abbreviated name of journal, volume number: page, year.* Book references should give author, title, edition number, city, publisher and year.

Illustrations (photographs, tables and graphs) should be submitted separately and not combined in the text. There should be a separate sheet entitled "Illustrations" which contains the various types of illustrations listed separately and numbered in the order in which they appear in the text. All photographs must be in black and white, clear cut, contrasting, and on glossy stock. Instructions for combining photographs are acceptable. Any number of illustrations over 4 are charged to the author. Combinations of photographs up to one-half page (6 x 4⅜ inches) count as 1 illustration.

Readers and Reviewers

The right is reserved to reject material submitted for reading or advertising columns. The views expressed in this journal do not necessarily represent those of the Minnesota State Medical Association or any of its constituents.

Advertisers and Subscribers

Classified advertising—15 cents a word; minimum charge $3.00; key number, 25c additional. Remittance should accompany order. Display advertising rates on request.

Annual Subscription—$5.00. Single copies—$0.50. Foreign and Canadian—$5.50.

Communications concerning advertising and subscriptions should be addressed to Minnesota Medicine, 2642 University Avenue, Saint Paul 14, Minnesota. Telephone Midway 6-2641.

Juvenile Delinquency

A Panel Discussion

It is hoped that this panel on juvenile delinquency will stimulate more thought and study on the primary causes of a nationwide problem.

HAROLD F. FLANAGAN, M.D., Moderator
JOHN K. DONOHUE, M.A.
HYMAN S. LIPPMAN, M.D.
LEONARD P. COWLEY, D.D., LL.D.

Presented at the Minnesota Academy of Medicine Meeting, Saint Paul, Minnesota, May 13, 1959.

WE are fortunate to have as members of our panel, men who have devoted much thought and time to a study of human behavior. They are particularly interested in the behavior of the child, adolescent, and young adult.

Mr. John Donohue, a man who for many years has had the responsibility of guiding, counseling, advising, and, if necessary, threatening those juveniles charged to him and his associates for rehabilitation by the Juvenile Court. His work as Chief Probation Officer of Ramsey County has been nationally recognized. He is the author of a text on juvenile delinquency, "Baffling Eyes of Youth," which was published by the Associated Press in 1957, and received the Leadership Award.

Dr. Hyman Lippman is a child psychiatrist who has probably worked with more problem children than any physician in the state. He is nationally recognized as a leader in child guidance. He is the director of the Wilder Child Guidance Clinic in Saint Paul, and Clinical Professor of the Department of Psychiatry and Department of Pediatrics at the University of Minnesota Medical School. He, too, is an author. His book, "The Treatment of the Child in Emotional Conflict," published by McGraw and Hill in 1956 has met with very favorable reception.

Bishop Leonard P. Cowley, the third member of our panel, has always had a great interest in the behavior of the child, especially the child during the adolescent age and young adulthood. He is a graduate of St. Thomas College, the St. Paul Seminary, and was a parish priest at St. Andrew's in St. Paul. Because of his interest in, and ability to work with youth, he was selected by the late Archbishop Murray to become the director of the Newman Foundation at the University of Minnesota. He was made pastor of St. Olaf's Parish in Minneapolis so he could be closer to his work at the University. His work here was so outstanding that it was only natural when a new Auxiliary Bishop to the diocese of Saint Paul was occasioned by the transfer of Bishop Byrne, he was selected for this honor.

Introduction

HAROLD F. FLANAGAN, M.D.
Saint Paul, Minnesota

The newspapers, the magazines, radio, and television constantly remind us of the abnormal behavior of our youth. Pediatric, psychiatric, and sociologic journals, in almost every issue, remind us of the importance of this subject with articles on the cause, symptoms, and treatment of juvenile delinquency. A discussion of this subject by those as well qualified as our guest speakers, seems timely.

On a panel discussion such as this, it is advisable to define our subject. For the purpose of our discussion, *juvenile delinquency* is that status of a boy or girl, under the age of eighteen, coming into contact with the law because of act or acts of deviant behavior against society. Delinquency can, and does, vary in severity and duration.

The term *delinquency* is not a pathologic or psychiatric term, but a sociologic one. In the lower socio-economic level, the term (as defined in the previous paragraph) is almost always used correctly. In the upper-middle, and upper-class social levels, the term *mentally disturbed child* is frequently substituted for *delinquent child.* In these cases the child is referred to a psychiatrist or to a school for disturbed children for therapy, and not taken through juvenile court. Since delinquency is a symptom and not a disease, we must consider what produces normal, as well as abnormal, behavior. The four institutions that play the major role in developing our emotional and social life, and are responsible for setting what standards of behavior we have are: (1) the home and its immediate environment, (2) the school, (3) the church, and (4) the state.

The first scientific study on the social cause of juvenile delinquency, was done in 1950 by Sheldon and Eleanor Glueck[1] of the Harvard School of Law. They studied several hundred boys from an institution, and using an equal number as a control, developed a classification of the social factors that are responsible for delinquency. With this classification, they were able to predict successfully a certain group of children who have as much as a 90 per cent chance of being delinquent, and by the same token, it was possible to predict those with a 90 per cent chance of improving their behavior.

The following is a copy of the Social Prediction Table as outlined by Dr. Preston McClendon.[2]

SOCIAL FACTOR PREDICTION TABLE

1.	*Discipline of Boy by Father*	
	Overstrict or erratic	71.8
	Lax	59.8
	Firm but kindly	9.3
2.	*Supervision of Boy by Mother*	
	Unsuitable	83.2
	Fair	57.2
	Close or suitable	9.9
3.	*Affection of Father for Boy*	
	Indifferent or hostile	75.9
	Warm (including overprotective)	33.8
4.	*Affection of Mother for Boy*	
	Indifferent or hostile	86.2
	Warm (including overprotective)	43.1
5.	*Cohesiveness of Family*	
	Unintegrated	96.9
	Some element of cohesion	61.3
	Cohesive	20.6

Discipline of Boy by Father.—

Overstrict or erratic: Father is harsh and unreasoning, demands obedience through fear, is not consistent in control.

Lax: Father is negligent and indifferent, lets boy do as he likes, or boy has not lived with his father at all.

Firm but kindly: Discipline based on sound reasoning which boy understands and accepts as fair.

Supervision of Boy by Mother.—

Unsuitable: Mother is careless, leaving boy to his own devices or in care of an irresponsible child or adult.

Fair: Mother, though home, gives or provides only partial care to boy.

Close: If mother does not work or is not ill, she personally keeps close watch on boy. If she works or is out of the home through illness, there is a responsible adult in charge.

Affection of Father and Mother for Boy.—

Indifferent: Parent does not pay much attention to boy, but is not outwardly hostile.

Hostile: Parent obviously rejects child.

Warm: Parent is outwardly sympathetic, kind, attached, even though in some cases overly protective.

Cohesiveness of Family.—

Unintegrated: Home is just a place to "hang your hat"; self-interest of members exceeds group interest. This applies especially to parents and older siblings.

Some elements of cohesion: Even if family group is not entirely intact (because of departure of one or more members for purely selfish reason) the remaining group has at least some of the characteristics of the cohesive family.

Cohesive: There is a strong "we" feeling among members; there is pride in the home. This applies even if the parent has never been a part (usually the father).

This prediction table shows in graphic detail the importance the home and the "child-parental" relationship has on behavior.

Dr. Adelaide Johnson[3] and others have introduced, through their correlated studies of parents and children, an extremely important concept of the etiology of juvenile delinquency. In many cases the child is only acting out unconsciously the unconscious impulses of the parent, with mutual gratification. There would appear to be another group of delinquents who are more consciously aware of the delinquent impulses of their parents. The impulses being revealed through parental behavior or repetitive stories related by the parent of their own or other's delinquent behavior.

Redl[4] has given us what appears to be our best sub-group classification. He describes four fundamentally different types of juvenile delinquency:

1. Basically healthy individuals whose delinquent behavior is a natural defense against wrong handling, a wrong setting in which to live, or against traumatic experiences of certain types.

2. Basically non-delinquent youngsters who are drifting into delinquent behavior on the basis of more acute adolescent growth confusion.

3. Delinquencies which are really on a neurotic basis, delinquent behavior as part of a neurosis or developed to disguise one.

4. Genuine delinquency—certain disturbances in the impulsive system of the individual, and/or malformation of ego, super-ego, ego ideal, in intensity or content.

Physicians generally have been slow in recognizing this important problem. All reports show the incidence increasing not only in frequency, but in the severity of acts committed against society. From 1948 to 1951 there was a 19 per cent increase in cases handled by the Juvenile Courts.

Those of us in pediatrics have been more aware of this condition than most of our colleagues, except the psychiatrist. The Academy of Pediatrics, six years ago set up a national committee under the chairmanship of Dr. Preston McClendon, to co-operate and work with ancillary groups in attacking this problem. Most state chapters of the Academy have local committees. For the Minnesota Chapter, Dr. Albert Shroeder is the chairman of the committee.

Some physicians doubt if juvenile delinquency is a medical problem. I am sure that those of us in the private practice of pediatrics, and those in general practice who work with children, recognize the importance of a knowledge of abnormal behavior patterns. The advances made in infant feeding in the past twenty years have reduced this from a major to a minor role in child care. But the increasing incidence of emotionally disturbed and delinquent children has shown us that we are neglecting a most important role in child development.

The pediatrician has not only the opportunity, but the duty to teach a healthy "child-parental" relationship beginning with his first examination of the newborn infant. The mother should be assured that she has the ability to care for her infant. She should be encouraged and advised to talk over problems that arise in the behavior of her child as freely as she reports on skin irritations or upper respiratory infections. The child's attitude may be as important as allergic symptoms. If the child has a physical handicap this should be discussed freely and completely with the parents, and with the child when he is old enough that he may make the adjustment necessary to live with his deformity. The pre-school examination offers the physician an excellent opportunity to discuss the child's emotional as well as his phyiscal problems.

There are two age-periods in the development of the child where behavior problems are more prone to manifest themselves. The first, the negativistic age that begins at about eighteen months and lasts until five to seven years of age, is characterized by the child resenting discipline. "No", "I won't", "shut up" are all not uncommon re-

sponses to directives or disciplinary advice. The second begins at puberty and adolescence where the rapid physical and physiologic changes frequently encountered, produce many emotional stresses. The awakening of sexual impulses add to the emotional problems of this age. The adolescent is frequently a medically-rejected age. The youth of this period needs advice and medical counseling, but he especially needs a doctor who will listen to his problems with a patient ear. This is a time when abnormal behavior may present itself and the physician should be aware of conditions that produce this, as well as those that produce physical problems. The early recognition of emotional problems and pre-delinquent behavior patterns offers the best chance for a cure. We in pediatrics are concerned with the growth and development of the child—but there is little reason to develop healthy bodies with intelligent minds if they are to be used in an undesirable way.

Causes of Juvenile Delinquency

JOHN K. DONOHUE, M.A.
Saint Paul, Minnesota

JUDGE Leonard Keyes of the Saint Paul Municipal Court claims *a juvenile delinquent is a young person who needs society's help so desperately that he strikes out against society in an effort to attract its attention.* In any event, delinquency is frequently the result of a state of mind and may have as causation factors—poor heredity or physical environment. More often the cause is social. Real crime and delinquency is a deep-seated disease requiring as much skill in treatment and as long a convalescence as tuberculosis.

The attention of civic leaders, youth workers, and law enforcement authorities is focused upon the delinquent and his gang. Movies, television, and magazines paint the exploits of these boys in sordid and lurid detail. Voices rise in alarm demanding vigorous and often drastic measures to combat the phenomenon. There is a sense of unquiet lest we be confronted with a new problem—a frightening by-product of a war and an era of shaken values and scarred character. However, the sociologist and criminologist know that times change but people do not.

A recent *St. Paul Dispatch* asked this question: "Is juvenile delinquency a sickness or sport." The article goes on to say that primarily it is sport, adventure, and a way of life.

A large majority of delinquents, according to six experts in the field, are essentially normal youngsters. They are just running with the gang and doing what comes naturally. The study commissioned by the National Education Association disclosed that only 25 per cent of the nation's delinquents demonstrate any degree of emotional disturbance. According to these experts 85 per cent of all delinquents come from lower-class families. It is unlikely that their parents will belong to a service or fraternal organization; the boy may quit school as soon as legally possible; his male relatives will not wear neckties, and he has not learned to save. The authors of the National Education Association report included a pediatrician, a criminologist, a psychologist, a sociologist, and a cultural anthoropolgist. They found that, of the 85 per cent of delinquents from lower-class families, 70 per cent were normal boys with bad gang associates; that only 15 per cent were emotionally disturbed.

The experts headed by Dr. William C. Kvaraceus, educator, defined the middle-class youngsters as those whose parents belong to service and fraternal groups, whose male relatives wore suits and neckties, who had roots in the community and whose source of money was an allowance.

They find an increase of delinquency among these boys and said that although they only committed 15 per cent of the total delinquencies, that two-thirds of the group committing delinquencies from the middle class were emotionally disturbed.

Those who know the lower-class delinquent, know that it is a truism that his activities always occur as a product of group involvement. The structure and behavior of the gang have not changed. What has changed is the technical skill needed for use in meeting its challenge. Man is a product of the social milieu. Delinquents can become good citizens if they have good leaders, for as Joseph Joubert said, "Children have more need of models than of critics."

Doctor Kvaraceus goes on to say in his study that if the present trend continues, it is likely that perhaps one boy in five will show a delinquency record by the time he reaches draft age.

You, as medical men, know that character begins in the home. While the psychiatrists and probation officers may play important parts in society's attempt to readjust the delinquent, prevention of delinquency must be the product of the co-operation of home, school, church, and pediatricians like Dr. Harold Flanagan, whose paper is presented here. Children are not potted plants which can be moved around the house, they grow outdoors with all the risks of contamination from the weeds and other plants in the garden, subject to countless outside influences.

The social prediction table of Sheldon and Eleanor Glueck lists discipline of a child by his father, supervision by his mother, affection of father for the child, affection of mother for the child, and family cohesiveness as essentials in the prediction of delinquency. I quite agree with the Gluecks' and Doctor Flanagan as to the utility of such a table.

Our grandparents lived in a patriarchy with few outside influences. Men grew to manhood without ever traveling 15 miles from home, and they died in their grandfather's house. Today we are flat, historically. One family in five moves across the county line each year. The working wife is the pattern, and dad is not the head of the family. Most of the household tasks are now divided between husband and wife. Only childbearing and mending are exclusively the woman's task—even his trousers have been taken from dad.

To the Gluecks' factors quoted by Doctor Flanagan, I would add something from an older prediction table of theirs, "age at first misbehavior and length of time intervening between the onset of delinquency and adequate social study." We in the Juvenile Court think this factor is essential.

In any event, the sad fact about our great "Century of the Child" is that the number of these true delinquents is increasing rather than declining. Not because parents love their children less, but rather because the child is less secure in essential areas. He lacks a belief in history and the firm base of an Old Testament religion. An individual set of moral standards has been replaced by the demands of group conformity often at the expense of personal integrity. Today's child often needs an authoritarian father and more control. He should have independence but he must know that there are limits as to what he is permitted to do and that his parents will hold him to these limits.

In the light of the present-day developments, including an expansion of gang warfare in the bigger cities and teen-age hoodlum behavior here, with and without autos, there can be little doubt that an evaluation of modern standards for the upbringing of youth is both appropriate and necessary. I wonder if happiness should truly be the *alpha* and *omega* of life. When a large percentage of the nation's children become habitually addicted to patterns of behavior that are considered particularly anti-social and undesirable, when Juvenile Court delinquency in Saint Paul shows an increase of 20 per cent as opposed to a school population increase of 3 per cent annually, we must seek the primary cause. It is most likely to be found within those institutions which are dedicated to the mental, moral, and physical development of children. Modern parents and teachers have found it expedient to adopt a *laissez-faire* attitude toward the problem of parental guidance —and control of children—almost as though parents and mentors feared the child. *Even law enforcement may become so permissive that the law becomes a joke.* When I was a kid the cops on the beat knew me and kept me good with my parents' co-operation. New York's police were told to be "pals" and they are now reaping the whirlwind. When a small boy is caught stealing cookies and is given a spanking, a spanking administered against a background of love, affection,

and security, he has learned an important lesson. He has learned that punishment is certain, that it can hurt, and that it may deprive him of his parents' smile of approval. Obvious rules administered by a fair elder, with punishment imminent for the violator, give the child true security. Every child needs a pat on the back, often enough, hard enough, and low enough.

Children should live in a community which protects them against physical dangers and moral hazards, in a home where they are loved and matter very much to someone, a good safe place in a family circle. The child whose emotional needs are fulfilled and who knows that there are limits to what he is permitted to do will not become a serious delinquent or neurotic.

Emotional Aspects of Juvenile Delinquency

HYMAN S. LIPPMAN, M.D.
Saint Paul, Minnesota

From the Amherst H. Wilder Child Guidance Clinic,
Saint Paul, Minnesota.

TO continue Dr. Flanagan's interesting discussion of juvenile delinquency, I wish to share with you my concepts of juvenile delinquency derived from clinical experience with disturbed youngsters who were referred to our Clinic because of anti-social behavior. Since ours is a psychiatric clinic, these children were referred because of the impression they had left with the court, social agencies, schools, and parents, that there were serious emotional components in their delinquent behavior.

As one works with disturbed acting-out adolescents, it is difficult to escape the conclusion that they are struggling to find a way of life that will keep them in a state of psychic equilibrium. They must find a way to deal with their deep feelings of bitterness and hostility that result from evidences of having been rejected and unwanted. They have a need to get even for the many hurts they have suffered. This does not refer to all juvenile delinquents; it does to the majority who are emotionally conflicted and anti-social. As we look at their surface behavior we see cynicism, bitterness, and coldness. As we study them carefully we become aware that underneath these feelings are uncertainty and deep anxiety. These young people realize that their chosen way of living is a precarious one that may end in disaster.

Leaving discussion of delinquency for a moment, I should like to discuss the basic emotional needs of all children, since these needs have not been met in the delinquent child. Every child has a marked need for affection, and acceptance from two good parents who love him and need him. The early weeks and months of maternal care help to make the child feel that he is loved, by the "mothering" which provides for his physical, as well as emotional, needs. The close relationship between the mother and child is essential in helping him to distinguish between self and non-self, to understand and accept reality, and to learn to relate to others. These qualities which the child develops through identifying with his mother will be of inestimable value to him in all of his future dealings with other individuals. A child who has difficulty in relating to others lacks an important means of learning to know and enjoy others. His ability to accept others stems from the early warm relationship to his mother. He learns to trust others from this trusting relationship.

Another important basic need for every growing child is to be able to express aggression and hostility; to recognize and respond to those who attack him. Aggression will be needed by him as he competes with others in the games that

he plays with other children and in his learning and working. Understanding parents will not be threatened by his aggression which has been modified through their care. They help him to guide and control his aggression.

A child has a need also to express his sexual drives. These budding sexual drives will find their expression in temporary periods of genital handling, masturbation, in a marked curiosity about the sexual differences between boys and girls, and an interest in both sexes. It will be through these experiences and through his relationship to both parents that he will learn to differentiate between the sexes and determine the different roles assigned to both sexes. Wise parents have learned that it is important to discuss the birth process in a logical, straight-forward manner with the growing child, answering his questions honestly and avoiding misrepresentation.

The normal child is not born with social interests. During the first year of his life very little is asked of him and he is primarily on the receiving end of the line. His demands are great and they are acceded to. This is important in helping him to feel secure. Soon, however, changes have to be instituted and he must learn to accept frustration and denial if he is to become a social being. He must learn that certain kinds of behavior are unacceptable, that he must share with others, and that many pleasures have to be denied.

As time goes on, he begins to have feelings of remorse when he does something unacceptable to his parents, such as hurting a brother or sister, or taking something that he should not be taking. This feeling of remorse becomes greater during the second and third year of his life, and finally he begins to feel guilty and upset when he does something that displeases his parents. These are the early stages of the development of a conscience or a super-ego, which causes him to feel guilt whenever he carries out an act which is contrary to the wishes of his parents. When this has occurred, one refers to the child as having developed a capacity to control his behavior—he has been socialized. This process of socialization is a *must* for the healthy, normal child. The development of the super-ego which I have sketchily described, will serve as an important aid to his ego in dealing with unacceptable instinctual drives. During this process of socialization he has learned to accept reality and has given up acting on the so-called pleasure principle. He has reached the stage in which he is able to give up immediate pleasures for future rewards.

Another aspect of the emotional development of the healthy child, and which is one of his basic needs, is to work through both positive and negative relationships to both parents. This is referred to as the Oedipus complex and it is crucial for his future relationship to his own and opposite sex, that he be able to deal adequately with this conflict. Freud showed very early that the failure to resolve this Oedipus complex is the chief underlying factor responsible for psychoneurotic illness. The healthy resolution of the Oedipus conflict will help the growing child to emancipate himself and his parents and establish normal heterosexual interests away from his family. During this process he will repress his sexual attachment to his mother, will become strongly identified with his father, and learn to accept authority from other father figures that he will meet in life. You will note that I have emphasized the role of the mother in the early developmental period of the child's life. Intensive studies of the young child justify the importance placed on this particular relationship in the child's life. The role of the father, which is very important, does not manifest itself nearly so much in the early months of the child's existence, as it will later on. During the early months the father's emotional support of the mother and his love for his child are important in helping the mother to carry out her responsibilities of mothering.

The conditions under which most juvenile delinquents are brought up are in sharp contrast to what the normal healthy child meets. Basic emotional needs are denied him. The homes lack warmth, comfort and an atmosphere of security. More often than not, the homes are broken by desertion, divorce, imprisonment, or institutionalization. Delinquency in the parents, neglect and lack of interest in family life create a setting that encourages the children to spend as much time as they can away from home in unsupervised settings. Under such conditions of tension and strife there is little motivation for the children to develop social standards; nor is much energy devoted to work or study.

When, in addition, the parents are overly severe and cruel in their punishment, aggression in the youngsters is more likely to be hostile and vicious. There is little concern about the welfare and

suffering of others. The problems of such anti-social youngsters whose aggression has not been neutralized by affection, is a serious one. It is one of the major concerns of social agencies and sociological research.

Child psychiatry has been more concerned with juvenile delinquency based on emotional conflict. The term *acting-out behavior* refers to emotional conflict which is acted out against others as a defense against having to internalize the conflict. The mechanism that makes it possible to displace conflict in this way is not yet clearly understood.

The family of the neurotic delinquent generally is quite different from that just described. The family is more intact, and an attempt has been made to help the child develop social standards. The pathology is more likely to be in one or both parents who are neurotic, and have created neurotic tensions and conflict in the home. Adelaide Johnson, Stanislaus Szurek, Edward Litin, and others have shown in their studies that often such parents unwittingly encourage delinquency in their youngsters in order to meet their own unconscious unsatisfied emotional needs for outlets denied them. To determine whether this is the underlying pathology or whether the problem lies in other emotional conflicts in the child, it is important to carefully assess the total life situation of the emotionally-delinquent child in order to locate conflict situations. Child guidance clinic staffs include social case workers, clinical psychologists, social group workers, and psychiatrists—in order to study every important aspect of the child's life. This includes the family, the school, and the community.

The most seriously disturbed youngsters—those whose conflicts are deep and fixed—do not respond well to psychotherapy. They require more intensive in-patient care over long periods in a setting where a variety of approaches in therapy can be utilized. Psychiatry of the future will have to devote much more time to research with these youngsters who are so very resistant to therapy. We know too little about them at present, and it is imperative that we know more. It is from this group that the serious sexual offenders and youngsters capable of the most wanton, cruel, and destructive behavior, come. This group also includes psychotic youngsters whose illness often begins with violent acting-out behavior.

In the process of describing conflicted acting-out youngsters, I should not overlook non-delinquent pre-adolescents and adolescents who are in emotional conflict. This is a problem of maturation in which the ego and super-ego attempt to deal with the sudden increased sexual demands during puberty. All the defenses which the ego has built up during the quiescent years from five to eleven years come into play, and often the picture is one of great turmoil. Anna Freud made an intensive study of prepubertal boys and has described the tension, panic, and psychotic-like behavior that may take place at this time. The period is a temporary one and lessens when the drives are satisfactorily mastered. During this period there may be an increase of aggression, destruction, cruelty, and acting-out behavior. If this is exaggerated and persists, psychiatric study and treatment is indicated. In most cases it does not persist.

As in other aspects of medicine, the treatment of juvenile delinquency starts with diagnosis to differentiate the environmental social factors from the personal intrapsychic ones. Most social agencies engaged in family and children's services are able to make this differentiation. When there is question about diagnosis, psychiatric services are requested. Many of you may be unaware of the strides social workers have made in the understanding of the dynamics of emotional conflict during the past twenty-five years.

Since the core of the problems of juvenile delinquency lies in the home, all services that help to strengthen the home help to lessen the development of delinquency. Every effort must be made to provide each child the affection and security he needs. Homes that are disorganized by delinquency, serious neglect, immaturity, and mental illness, are sore spots in the community and require special care. Saint Paul has done excellent research with a large group of such families during the past few years, with funds contributed by the Hill Family Foundation. The project is called the Family Centered Project, and is widely known throughout the country. This study has demonstrated that the disorganized families, after initial resistance, gladly accept the services of well-trained case workers. The number of such families that one worker can reach is small as compared to case loads in the average public welfare agency; twenty is the largest number that can be adequately serviced. I recommend that you read the reports of this Project which, among other accomplishments, has helped materially to

reduce juvenile delinquency in these families. In view of the dangers involved if a child cannot be provided his basic emotional needs, whenever case work establishes the fact that parents are inadequate to raise a child and cannot respond to casework treatment, the child must be removed from his home and placed in a suitable foster home.

Most agencies working with juvenile delinquents and their families need more staff to even approximate adequate services. It is ridiculous to ask a well-trained probation officer to deal with seventy-five to 100 juveniles who have started in careers of crime. There is no opportunity to even know the members of the families of these youngsters and their problems, let alone know the emotional needs and conflicts of the youngsters themselves. The same applies to all social agencies who work with families needing intensive help.

Institutions for delinquents need large numbers of trained social workers in addition to psychologic and psychiatric services. Nothing can take the place of a warm daily personal contact with these institutionalized youngsters, many of whom are reaching out for help. Youngsters who have always been deprived of affection would have a reasonable chance to find themselves by identifying with an adult who shows a genuine interest in them and maintains this interest—a new experience for most of them. If this interest could continue after leaving the institution, the gains could be even greater.

I feel quite confident that if society were really interested in doing something about the delinquency problem, significant gains in prevention and treatment could be made by putting into effect all the knowledge gained by sociologic research, social work and psychiatric clinical studies. Unfortunately, society is either not well enough informed about this knowledge, or for reasons that are not clear, does not insist that required action be taken.

In the meantime, psychiatry will continue to seek for more effective methods for dealing with the serious emotional intrapsychic factors that produce and maintain anti-social behavior. It is good that the general medical profession is concerning itself with this problem as manifested by this panel discussion.

Juvenile Delinquency and the Clergyman

LEONARD PHILIP COWLEY, D.D.
Saint Paul, Minnesota

Most Reverend Leonard Philip Cowley is titular Bishop of Pertusa and Auxiliary to the Archbishop of Saint Paul.

IT IS NOT the purpose of this discussion to define juvenile delinquency, so we shall just accept as subject matter those who are spoken of generally as juvenile delinquents. Although the clergyman is not always the best person to turn to in the counseling of problem children, he nevertheles is a natural resource person for many people because of his spiritual relationship to his parishioners. We may say that he is "not always the right person" because many clergymen have not received the specialized training for guidance in youth problems which have a clinical cause and effect basis. Moreover, many clergymen, in the pursuit of holiness for themselves, which people have a right to expect in their pastors, cannot easily conceive the complex causes of behavior which seem merely irreligious. I would say at the outset that this is not necessarily a defect in a clergyman because it is a perfectly respectable expectation that ministers, rabbis, and priests be concerned with sanctity and spiritual progress first and that which impedes it second.

Therefore, it is a wise pastor who recognizes his own limitations in the spiritual guidance of difficult persons of all ages. He would then, it is to be expected, make the proper referrals to those experts whose work it is to deal directly with those who deviate in what we may call a clinical manner. I say "clinical manner" to show a difference between behavior which may deviate in an understandable manner. The second kind of deviation can be handled easily by all who are interested in their fellow men, and clergymen, of course, are specially suited to this kind of guidance.

Experience in spiritual guidance should teach the difference between these two kinds of deviations. For example, if I were to be called upon to help in the counseling of a lad designated correctly or wrongly as a juvenile delinquent, I would be specially careful to make a judgment that I was either competent or incompetent to handle the case. If I should judge at once that I have a clinical case on my hands, or indeed after several interviews, I would immediately search for a resource person or institution that could cope with the problem as soon as possible. I would be aware that if I were incompetent and did not make a proper referral I may either delay effective counseling or further complicate the problem by oversimplifying it.

This is not to say that a clergyman should be reluctant to give guidance to delinquents or that he should be always fearful that by counseling he is encroaching on another field. Actually there are many cases which involve simple problems which arise out of normal causality that a clergyman is far more competent to handle than a clinician. The science of clinical counseling is a very young one indeed and is still struggling for formation. The structure of the science is far from a static one. Although great progress has been made, there are still lacunae which spell caution. It is entirely possible that a particular problem lad may not be so much a problem as would appear. If he were subjected to some clinical processes without necessity, it could well precipitate him into a difficulty that would permanize what otherwise might have been a transitory ailment.

It would seem that teamwork by clergymen and the various kinds of clinician would be the ideal set-up in handling juvenile problems. We are well aware that the psychological sciences are fearful of the bungling of clergymen, but there exists along with this fear the anxiety of clergymen that psychological scientists will rob people of the spiritual formation and motivation that have sustained men for many centuries. This seeming conflict is an unfortunate one because a humble counselor, whether he be a clergyman or a psychiatrist, will readily understand the role of his counterpart and will not hesitate to make wise referrals when this is indicated.

Often the seeming conflict we have described grows from an ignorance of the purposes and techniques which are set forth. The conflict is furthered by the complications of language. If, however, one is concerned enough about this conflict to resolve it, one will readily see that the frames of reference, or language, can be misleading, for the fundamental ideas expressed in the different forms of language are close to identical. Those afraid of Freudian language, for example, will insist that this excludes the conscience. Yet, the superego of Freud is easily conscience to the clergyman. Free will is easily ambivalence.

From what I have said, I would like to prove that there is no conflict among humble scholars who presume to help in the spiritual life of others. Whether the motivation be religious or clinical the aim is, or should be, high moral character and spiritual comfort. Lest this be misunderstood as too broad a point of view for a clergyman, may I say that the final concern of a dedicated minister, rabbi, or priest is the supernatural disposition of the soul. The common interest of religion *and* science is to establish a natural hygiene of the soul. We are very happy to hear in this discussion the profound observations of Dr. Lippman who has dedicated himself in such a renowned and successful way to the care of youth behavior. We are likewise grateful to learn from the long experience of Mr. Donohue what the problems are from a social worker's point of view in observing a young person in relation to his family and community.

I think all of us feel a great security in the guidance of a psychiatrist because of our assurance that the physical well being of the child is known and evaluated since so often the roots of disturbance are physical. The psychologists often can contribute a deep insight from their knowledge of the behavior patterns established by research. The psychiatric social worker, a newcomer to the

team, can often be the most important factor in child guidance because he has the opportunity to observe the surroundings of the subject, the smallest element of which may be the cause of the disturbance. The clergyman very often is the shortest way to a problem because his rapport with the subject has often been long established, and the subject finds it easy and comfortable to relate to him. All these principals together make up the ideal team to work in counseling and guidance.

In trying to understand the young person who is disturbed, or who has fallen into trouble, it is necessary to isolate the individual theoretically from his environment. That we might better understand his identity *per se* is important, also that we try to conclude what is the subject's evaluation of himself. Then we proceed to see what is essentially and what is accidentally identified with him and his experience. This opens the whole vista of environment. The force of heredity, though greatly exaggerated, ought to be judged. At least it is of some good to know the physical and psychological antecedence of a subject. The known and unknown influence of parents must be studied thoroughly. Theories of pattern relationship ought to be explored. Socialization of the subject with all his necessary and chosen acquaintances ought earnestly to be examined. This, of course, is especially important because socialization is not only an important factor in the maturation of children, but often can be reworked for the solution of children's problems.

I would think that this recipe for the examining of all children, as well as only those with problems, would be the common methodology of all counselors. Each kind of respectable counselor can contribute in this common technique.

I think it can be said that light or surface neuroses can be handled effectively by properly qualified clergymen. My caution to any clergyman would be to seek help or make referrals if there is evidence of deeper neurosis, and certainly any kind of psychosis.

Whether we are talking professionally or non-professionally about juvenile delinquency, we must certainly not press the panic button. If we have a special problem in juvenile delinquency today it calls for clear unprejudiced thought and action. Let us not look for too much from legislation. Legislation limits only outward visible activity. The solution is to inform and keep informing as many people as possible that behavior is in individuals. Establishing a climate in the home or in the city for good sound behavior is important. This is not done by legislation. This is done by personal appeal to those who understand the ravages of unordered environment. Despair should find no place in the attempts to do this because actually in spite of all that is being released by our news agencies, there is reason to think that there is a growing improvement, at least in some quarters. When a problem arises in a well ordered environment, it is easily discernible and, like cancer, can often be cured or cared for if caught early enough. Problems which emerge from a chaotic environment should be coped with when and if possible. Our hope is that we shall gradually be able to intrude on the chaos and all of us together make a progress of which we can be proud.

I realize that I am talking to a group of medics, and I should like to say to you that the clergymen in your community must be reckoned with. Personally, of course, you are free to associate with them or not, but officially by your professions, you are thrown in with them. Your patients are their flocks. Many of the clergy are eminently attractive because of their holiness, education, winsome ways, community interests, or what not. Others will be difficult to understand, not specially friendly to you or your practice, or seemingly inimical to scientific progress. You cannot write them off. And how often you may have to turn to them for their help in dealing with your patients! The clergy needs enlightenment, but so do physicians.

Generally, I think you will find that the clergy is flattered by any friendly word or act you extend to them. They will be happy to respond in kind. It gets down to this. You need them and they need you. We have much to learn from one another.

May I add that as often as the clergy need physicians the physician may stand in need of the ministrations of his minister, rabbi or priest. The sooner the old conflict of science versus religion is buried the better off all of us will be.

Juvenile delinquency (to get back to that) is a medical problem, a social problem, and a religious problem.

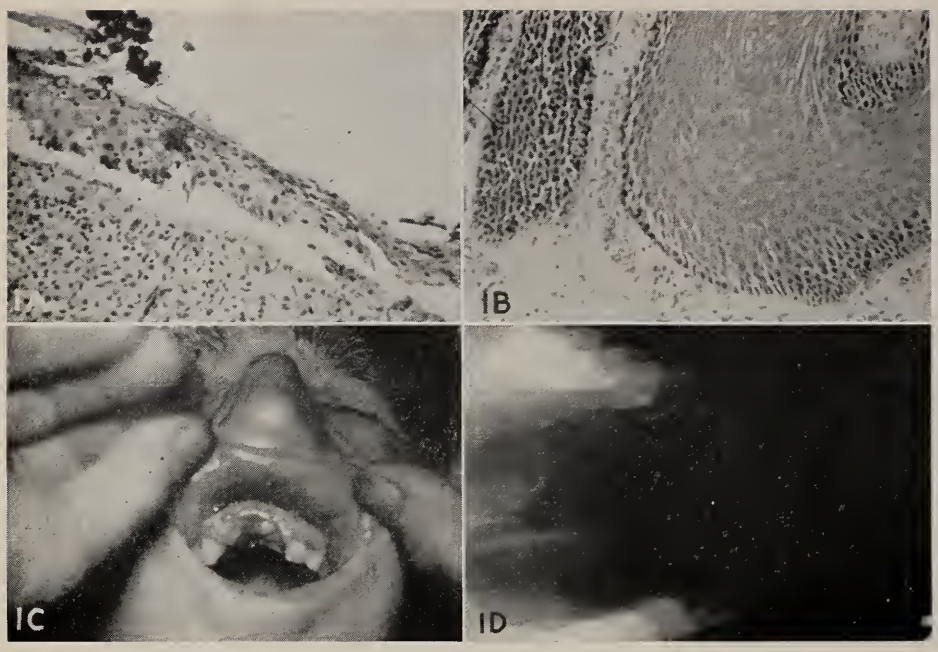

Fig. 1. (A). Early squamous cell cancer of the intradental buccal area showing bowenoid changes with nuclei of varying sizes and shapes. (B). Verrucous carcinoma showing marked activity in the basal cell areas with hyperchromatic nuclei and deep projection of acanthotic epithelium into the underlying connective tissue. (C). A large squamous cell (P_2N_0) on the upper anterior gingiva. Patient had upper teeth removed before the course of radiation. (D). Radiograph of the same case showing destructive process involving the hard palate. Patient has a one-year cure of the lesion with combined x-ray and external radium application.

Carcinoma of the Oral Cavity

Part I

● *Conclusions after the care of 783 patients*

THE TREATMENT of cancer of the oral cavity is a complex problem: It is viewed by some as a hopeless task and not one to increase one's popularity or reputation. Yet for the past forty years our group has felt that we must take the difficult treatment problems in cancer therapy, as well as the much easier and more rewarding assignment of curing basal cell and squamous cell cancers of the skin. We have inherited from our predecessors adequate facilities, experience derived from early experimental treatment with various methods and a reputation in the community which we must uphold.[1] We have answered the challenge and, although discouraging at times, it has produced gratifying results.

A. J. Gardham's[2] classification of neoplasms in the buccal cavity has been a guidepost, especially to those who approach this problem from a radiation viewpoint. He divides these lesions into:

Group I. Neoplasms which are:

1. Accessible.

2. Do not show signs of high malignancy in regard to spread, metastasis and reaction to treatment.

3. Do not show signs of high malignancy in their microscopic picture (Grade I). This includes most cancers of the lip, most cancers in the inner

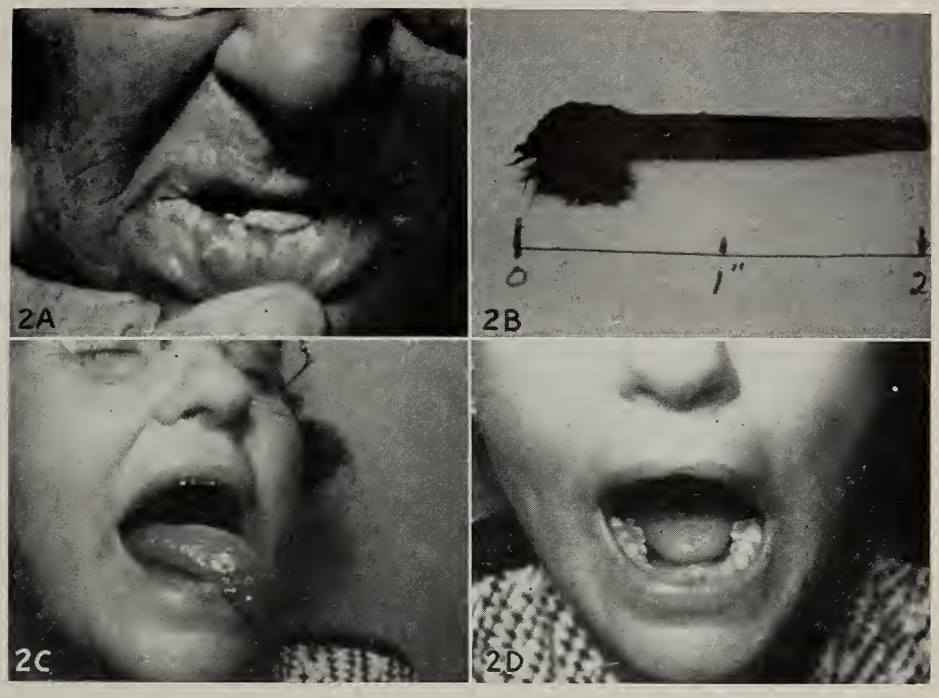

Fig. 2 (A). Verrucous carcinoma arising in various areas on the inner surface of the lower lip and each intradental line in old leukokeratosis resulting from years of dipping snuff. (B). A brush used to dip snuff made from the root of a redbud tree (length 2 inches). (C). Squamous cell carcinoma arising in leukokeratosis at the edge of the tongue in a patient with a narrow space between the lower bicuspid and molar areas. (D). Lower inverted teeth producing a sharp, razor-like edge. The patient was first treated with radiation, but teeth were not removed. The lesion immediately recurred. Before further treatment was successful, the irritating bicuspids were removed.

JOHN H. LAMB, M.D.
DWANE B. MINOR, M.D.
Oklahoma City, Oklahoma

Presented at "A Cancer Symposium for Dermatologists", September, 1957, Department of Dermatology, University of Minnesota, honoring Henry E. Michelson, M.D., retiring professor.

cheeks, and some cancers situated on the anterior two-thirds of the tongue.

Group II.—Neoplasms which are inaccessible but still do not show signs of high malignancy. This would include cancer of the floor of the mouth, epiglottis and pharyngeal areas. If they do not involve the bone they may be cured by radiation.

Group III.—Neoplasms of high malignancy.

1. Microscopically Grade III and Grade IV cancer of the lower jaw, submucous infiltrating lesions of the nasopharynx, posterior one-third of the tongue, and the lesions of the upper jaw.

2. Five-year survival in this group is negligible with either radiation or surgery.

3. Striking long-term survival has been produced by palliative radiation therapy with radium and filtered x-rays, plus the co-operation of a conservative cancer surgeon who appreciates the use of the two aforementioned modalities. He waits until the radiation effects have produced all of their results, then decides what procedure to follow.

Group I is the field in which we have been interested; the cure rates have been surprisingly high, expense to the patient is low, and the minimal loss of tissue remarkable. All of our cases have been seen in private practice; therefore, the

cases are seen early, the lesions are smaller than those observed in a group of charity patients, and the prognosis is much better for cure. Decisions as to treatment are made from a radiological viewpoint. If surgery is deemed advisable later on, a surgeon is called in consultation to see the case before it is treated with radiation. His advice many times is accepted by us, although many times not by the patient.

Pathology

The pathological changes for the most part in our buccal malignancies are compatible with squamous cell carcinoma Grade I. The changes are minimal according to criteria for skin cancer, and the general pathologist may make a diagnosis of leukoplakia or leukokeratosis even though clinically there is induration, a rounded border (at times ulceration), and is clinically diagnostic of cancer. We must then understand the normal pathology of the mucous membranes.[3] There is no normal keratin produced in the mouth except in the epithelium of the gingival borders. When we see hyperkeratosis with parakeratosis, it indicates an early malignant change and this means much more than when seen in precanceroses of the skin where production of keratin is normal.

Montgomery[4] states that when cancer supervenes in leukokeratosis, it is not manifest by cords and strands breaking through to the underlying corium but is often seen intra-epithelially, "cancer *in situ*," with features of Bowen's disease, variability in size and shape of the epithelial cells, and large, giant type, nuclear arrangement (Fig. 1-A) with heavy chromatin content, but usually showing epithelial bridges. Cipollaro and Foster[5] have also stressed these "bowenoid" changes in the mucosa.

A second group of oral squamous cell type cancer (intra-epithelial) is one in which the pathological changes are rarely recognized as a malignancy. This group is described by Ackerman[6] and others as Verrucous Carcinoma. It comprises a high percentage of the mouth cancers we are called upon to treat. The lesions occur predominantly in aged men or women, most commonly on previous leukoplakia of the buccal mucosa and lower gingiva. Use of tobacco for years is significant etiologically. Slow-growing, verrucous in character and often extensive, this neoplasm tends to involve local structures (mandible and soft tissues). Distant metastasis seldom occurs and local lymph node metastases are rare. Microscopically, they show a well-differentiated epithelium with an intact basement membrane; the basal and Malpighian cells of the epithelium usually show a tendency to hyperactivity (Fig. 1-B), loss of polarity and increased chromatin content. Small biopsies are always reported benign and only by studying a tumor removed in toto is the true invasive malignant nature of these benign-appearing growths shown; however, in total surgical removal the danger of recurrence is probable.

Ackerman reported that there are local recurrences in inadequately treated patients in a high percentage of cases: Out of fourteen patients he treated with roentgen rays alone, eight suffered recurrences (57 per cent). He therefore advises surgery for all but the very small lesions, but his surgically treated patients also suffered recurrences. Therefore, it behooves the physician treating cancer of the mouth to stand on his own clinical diagnosis of carcinoma. He must make his decision of radiation treatment to a cancer on past history, that is, the use of tobacco, rubbing dentures, carious, sharp teeth, the progress of the lesion and the clinical appearance.

The therapist must study his own microscopic slides and be aware that any changes in the keratotic layers, namely, parakeratosis, activity in the basal cell layer, any "bowenoid" changes in the epithelium, must be taken as a carcinoma and treated as such. Early adequate treatment of all borderline lesions is recommended in the face of benign reports from the pathologist rather than procrastination in awaiting a biopsy report that would be called by many the only basis for therapy of a cancer. The x-ray therapist's responsibility is to his patient, and if bad results are encountered by waiting, the therapist must bear the blame, not the pathologist.

The importance of a positive biopsy report on a medico-legal basis has been overstressed. The jury is not interested in medical arguments of borderline lesions, but is instructed as to the integrity of the physician and his reputation for treating cancer over the years. A pathologist who recognizes these pitfalls, that is, difficulty in diagnosis in the mouth, is a great asset to the therapeutist in this situation.

Out of fifty-four cases studied in the 1949 to 1954 series, twenty-three biopsies were recorded. Many of the thirty-one cases without biopsies included very aged people who refused any operation involving an incision. Several had religious scruples against any surgery, but radiation was "God's mysterious light" and was permissible.

Then a certain percentage were in areas on which it was deemed dangerous to disturb the tumor bed; that is, transitional Grade III or Grade IV, rapidly growing squamous cell cancers in the posterior tongue area, tonsillar pillars, floor of the mouth, and gingival lesions of the lower jaw. In these cases the fear of metastasis from biopsy is still considered to be of importance. Of the twenty-four biopsied cases, the records show:

TABLE I. LOCATION OF ORAL CANCER STUDIED IN THREE GROUPS (1944-1949, 1949-1954, AND 1954-1959)

Period in Years	Buccal			Tongue			Floor of Mouth	Palatine	
	Ant	Mid	Post	Ant	Mid	Post		Ant	Post
1944-1949	18	37	14	2	2		11

Squamous cell cancer, Grade III-IV	5
Verrucous carcinoma	4
Glandular adrenocarcinoma	1

Etiology of Oral Cancer

There are definite borderline lesions in the mouth which may be classified as so-called precanceroses, but one must always veer toward the malignant side in all oral lesions. In listing precanceroses in the mouth, nearly all malignancies arise from leukoplakia,[3] then to thickening and leukokeratosis, and finally cancer; consequently we can say that the main precancerous lesion in the mouth is leukoplakia. Large, verrucous lesions are nearly always cancer, but small, punctate verrucae may occur in the hard palate area and about the floor of the mouth. These are usually soft and sessile and clinically a differentiation can be made.[7] I have seen very few malignancies in the mouth arising from so-called small verrucae.

In July 1953 at the International Congress of Radiology in Copenhagen,[8] the committee on Stage Grouping in Cancer and Presentation of the Results of Treatment of Cancer adopted certain alphabetical and numerical figures to simplify the presentation of cancer cases of the breast, larynx, and cervix uteri. The following classification is a composite of those suggested by the International Committee on Presentation of Results of Treatment of Cancer International Congress of Radiology in 1953 and was used in the presentation of results in oral cancer at the American Radium Society in 1959 by MacComb and Fletcher.[9] It will be used in this paper also to simplify presentation of our results. For squamous cell carcinoma occurring in the mouth first the size of the lesion is described by the letter and number:

P_1—3 cm. or less in size.
P_2—3 to 5 cm. in size.
P_3—Above 5 cm. in size.
P_4—Massive extension.

The lack of any palpable lymph nodes or their appearance is tabulated by:

N_0—No palpable nodes.
N_1—One single node small to moderate size, less than 2 cm., situated unilaterally.
N_2—Large, unilateral, movable node above 2 cm. in size, or multiple unilateral nodes.
N_3—Bilateral nodes, or fixed unilateral nodes more than 2 cm. in size.
N_4—Distant metastasis.

Location of Oral Cancers

The location of oral cancer has been found to be in the greater percentage of cases on (1) the sides of the buccal cavity, (2) along the interdental line, and (3) the tip and sides of the tongue.

The buccal surface was divided into anterior, middle and posterior. From 1944 to 1959, a total of twenty-eight cases was located on the anterior buccal surfaces, sixty-eight cases on the middle, and twenty-seven on the posterior surface.

For the same period, the tongue was the loca-

tion for a total of twenty-three cancers on the anterior portion, with eleven on the middle third, and a low percentage on the posterior third of only seven.

The palatine area was divided into the anterior or hard palate region on which only four cancers were recorded; on the posterior or soft palate area, seven cases; inside the lower lip three cancers were seen.

On the gingival area the cancers were divided between those on the upper and lower gingiva (Fig. 1-C and D); three patients were seen with cancers on the upper gingiva, and ten patients were seen on the lower. In the gingival area the cancer sometimes is cured by radiation alone. The vast majority of these malignancies is Grade I squamous cell carcinoma; however, some of the lesions are of the penetrating, burrowing, verrucous type cancers which clear with radiation, then recur and finally involve the underlying bone. However, in several instances on the lower gingiva, they have been cured following recurrence from irradiation by surgical removal of over one-third of the mandible.

Cancer of the lip was seen the most frequently with excellent results from radiation; 318 patients[10] were studied in detail; actual cancer deaths recorded were only twenty-two, with a determinate cure rate of 93 per cent, but an actual five-year cure rate of only 70.5 per cent. Many older patients were lost from other diseases before the five-year period was up, while numerous others moved out of the state and contact with them was lost; however, through the years 1944 to 1959, we feel that our determinate cure rate in cancer of the lip was in the 98 per cent bracket.

When a metastasis was evident in our lip cancer patients, a yearly total of sixty cases, they always reported to us immediately. We have seen only one or two patients per year in the past fifteen years who have had metastasis following therapy with a combination of x-rays and interstitial radium needles locally, plus prophylactic x-rays to the gland-bearing areas. In this period (1944 to 1959) we have treated a total of 554 lip cancers, a total of 229 oral cancers, and a combined total of lip and mouth cancers of 783.

A study (Table II) was made of eighty-four cases of oral cancer treated with radium, both with external radium applications and interstitial radium needles, and x-rays from the years 1944 to 1949. At that time there was a great variation in the treatment of each case by various members of our group; some were treated with electrosurgery followed by filtered x-rays; some by radium applications. Another group was treated with interstitial needles without combination with x-rays, and it was impossible to work up any data on therapy and results. However, in this group it was interesting that forty-nine cases had no signs of metastasis on first examination clinically (N_0), with no lymph nodes palpable in either submaxillary region. Thirty-five of the cases had a suspicious node or nodes in the lymph drainage areas in the submaxillary and submental regions. Many of these suspicious nodes completely disappeared after irradiation; others remained for the duration of the patient's lifetime (after several courses of roentgen therapy to the involved node) without any regrowth, but there was still an indurated area that could be palpated. Others, where surgical excision was refused, have completely disappeared with several subsequent x-ray series windowed closely to the node. Several were treated with 6000 r from interstitial radium implants and were cured.

In the second series studied (1949 to 1954) only nineteen cases (Table II) of the fifty-four total cases showed a palpable suspicious node or nodes; possible metastasis (N_1 to N_3). Of this group (Table IV), eight later died with cancer metastasis; of the other six who died of oral cancer, the metastatic nodes appeared from three months to seven years after the original examination.

Causes of Oral Cancer

1. *The Use of Tobacco.*—The etiologic factors in oral cancer (1944 to 1954) are tabulated in Table II; a total of seventy-four patients gave a history of using tobacco. Pipe smoking (twenty-six cases) seemed to produce the highest number of malignancies. It is felt that heat from pipe smoking is the causative factor in cancer of the mouth. The area usually is localized to the point where the pipe is held; therefore, the lesions are as a rule in the interdental line in the buccal areas and over the gingiva or on each side of the tongue and the floor of the mouth.

In cigarette smokers, a total of eighteen cases, the malignancies usually arose in each buccal commissure or posteriorly on the tongue, or the posterior tonsillar-buccal area. In all of these cases in which smoking seems to be a factor the patients are asked to discontinue this habit; however, this was a difficult task and some never accomplished it.

The sixteen snuff dippers were all women from seventy to eighty years of age (Fig. 2-A). This is probably the most difficult habit of all to break; many patients would rather dip snuff than eat.

There was a malocclusion or a narrowing of the horizontal plane of the floor of the mouth in five cases of cancer of the tongue. The lower molars and bicuspids angled inward on each side, thereby

TABLE II. ETIOLOGIC FACTORS ENCOUNTERED IN CANCER OF MOUTH

Period In Years	Male	Female	Size of Primary Cancer in cms.				Palpable Nodes When First Examined				Tobacco Users				
			1½	2	3	5	N_0	N_1	N_2	N_3	Snuff	Pipe	Cig.	Cigar	Tobacco Chewers
1944-1949	58	26		P_1		P_2	49	35	—	—	7	15	10	5	2
1949-1954	34	20	12	18	12	2	35	19	—	—	9	11	8	2	5

Period in Years	Rubbing Plates	Malocclusion	Rough Sharp Teeth	Plus Dental Caries	Chronic Histo-plasmosis	Galvinism	Alcoholism	Serology ††††	Under Arsenical Therapy	Serology Neg.
1944-1949	14	5	13	14		2				
1949-1954	13		7	7	1	3	1	4	2	6

Therefore, a great factor of avitaminosis both of B Complex and C in these cases was present. It is felt that in all of these older people, if the cancers are cured, they should receive multiple vitamins orally with mineral contents in proper proportions. At the same time they should receive ten to fifteen units of crude liver extract once or twice weekly parenterally.

Snuff is composed of the residues of the leaves, and stems of tobacco plants, and seems to contain more irritating substances than plain leaf tobacco; thus, it may be more irritating than plain tobacco from the leaves. (Figure 2-B) shows the redbud root, two inches long, which makes an excellent applicator. It is moistened and this is then dipped into the snuff box and placed in the oral cavity with the stick end of the root protruding from the mouth. The older this applicator becomes in use the better it is thought to be. Cigar smokers and tobacco chewers make up the small proportion of tobacco users—seven patients each.

2. *Rubbing Dentures, Malocclusion and Sharp Teeth.*—The rubbing of artificial dentures, the presence of sharp, ragged teeth and malocclusion of the teeth were thought to be the causative factors in fifty-nine cases of oral cancer; twenty cases showed sharp, carious teeth in close proximity to the area of the cancer growth. Many of the articles on radiation treatment of cancer of the mouth suggest extraction of carious teeth preceding radiation therapy. Obviously sharp, ragged teeth causing direct trauma should be eliminated; rounding off the sharp points is preferred to extractions.

causing a saw-like action on the tongue as it goes in and out of the mouth (Fig. 2 C and D). It is felt that the teeth causing this trauma to the tongue must be removed, and, if there is a malignancy present, they should be left out permanently. No partial dentures are advised.

3. *Carious Teeth.*—Carious teeth were the positive etiologic factor in twenty-two patients of oral cancer (Table II). In our experience, however, when a patient comes to us for treatment of cancer of the mouth, we feel that damage from old, carious teeth in most instances has already been done; that a certain immunity to the variable micro-organisms, that is, bacteria, actinomycosis, spirochetal and leptothrix organisms, is present and that extensive extractions may be extremely dangerous unless there are very few teeth and they can be removed easily. Therefore, 95 per cent of the time in our practice the teeth are left intact before radiation therapy is instituted, but local measures are taken to clean up the mouth such as washing of the teeth twice daily with tooth paste. We have seen only a few cases of osteomyelitis or radionecrosis of the mandible following radiation. If the teeth need to be removed later, a period of three or four years is allowed to elapse following radiation before extraction. It has been our observation with those who have artificial dentures that, after the malignancy in the oral cavity has been cured, the danger from rubbing plates causing a recurrence of the cancer is probable; consequently, the patient is not allowed to wear the artificial dentures again excepting for short intervals as in the case of a special public appearance.

4. *Galvanism.*—The effect of electric galvanic currents between dissimilar metals in the mouth was a definite factor in the cause of leukoplakia, leukokeratosis and cancer in the mouth in five patients (Table II). Figure 3-A shows a squamous cell carcinoma arising immediately adjacent to the gold fillings. There were many amalgam fillings in this patient's mouth which showed from 20 to 30 microamperes of current running towards this gold filling immediately adjacent to the squamous cell tongue cancer. Lain, [11-15] emphasizes the importance of this factor in oral leukoplakia and cancer. It is felt that when the amalgam fillings are being disintegrated by the galvanic current from dissimilar metals that the tin and nickel of the amalgams become ionized. These ionized metals pass into the saliva and become deposited in the tissues of the gums or tongue, causing (1) a metal irritation, (2) leukoplakia, and (3) eventually cancer.

Burkett[6] describes a case in an electrician who developed a leukoplakia on the tongue which was thought to be due to testing the electrical potential of batteries (galvanic current) by applying his tongue to two wires connected to the positive and negative poles of the battery.

Several other minor etiologic factors in the production of oral cancer must be considered. It is the opinion of MacComb and Fletcher[9] and others that the chronic use of alcohol is an important cause of mouth cancer, although it is rarely recorded in our two series. It is a question which has not been asked frequently enough in our cases and it is, I believe, a much more common occurrence in these cases than was previously suspected. Leukoplakia of the tongue with subsequent cancer has been stressed, occurring especially in syphilitics; however, only four cases in the later series were encountered in which the Wassermann reaction was positive. Two of the cases were undergoing arsenical forms of therapy when they reported with cancer of the tongue. In one case (Fig. 3-B), the lesion was treated with arsenicals for nine months as a gumma before cancer was finally suspected. One of our cancer deaths recorded was this patient. In our experience, the simultaneous diseases of syphilis and cancer have always given a poor prognosis.

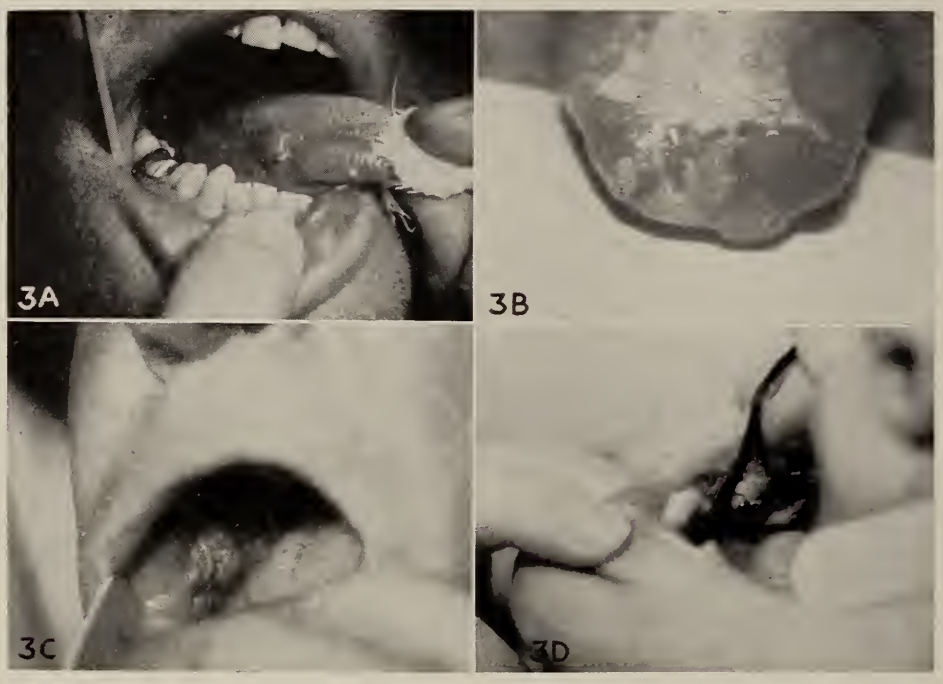

Fig. 3. (A). Squamous cell carcinoma arising at the side of the tongue in direct contact with a gold crown. A high galvanic current of 30 to 40 microamperes was registered between this gold crown and surrounding amalgam fillings in other teeth. (B). Case 54, the first of three squamous cell carcinomas, 1.5 cm. in size, P_1N_0, on the tip of the tongue as recorded in Table IV. Leukokeratosis covers almost the entire surface of the tongue. Patient had been under treatment for syphilis for several years. (C). Squamous cell carcinoma arising on the inner buccal surface in a pipe smoker. (D). The same lesion with insertion of interstitial radium element needles.

(To be concluded in the March issue)

Nutritional Requirements of the Neonate

TABLE I. UNDESIRABLE TRENDS IN INFANT FEEDING

Failure to dilute and/or add CHO
Formulas of excessive caloric potency
High protein
High carbohydrate
Unreasonably early introduction of solid foods
Unreasonable promotion of products of unproven worth
Appetite—growth stimulators

● *Breast feeding is the ideal regimen for a neonate. Failing that, the simplest artificial feeding regimen employing humanized cow's milk should be employed. Ordinarily, only Vitamins C and D are essential supplements. The importance of essential fatty acids is becoming increasingly appreciated.*

THEODORE C. PANOS, M.D.
Little Rock, Arkansas

From the Department of Pediatrics, University of Arkansas Medical Center, Little Rock, Arkansas.
Northwestern Pediatric Society Lecture, presented before the Minnesota State Medical Association, Duluth, Minnesota, May 27, 1959.

THE FACT THAT a portion of this program can be devoted to a discussion of the nutritional requirements of the first four weeks of life signalizes the sensational progress which has been made in the field of infant feeding. Only a few decades ago, the complexities and hazards involved in the use of artificially prepared milk mixtures constituted the most compelling indication for the establishment of breast feeding. Practitioners of that time were engrossed in the intricacies of juggling the various constituents of a formula and supervising its concoction. The whole procedure represented, in a sense, both a mathematical science and a fine art.

Over the years, as a result of prodigious studies in research and processing technology, the artificial feeding of infants has become a safe, simple and eminently successful procedure which is quite standardized. Indeed, it has proved so successful that question of the desirability and advantages of breast-feeding appears to have been generally relegated to the realm of philosophic, ethical or psychologic considerations, in spite of certain definite pragmatic superiorities. Actually, from a nutritional point of view, little can be said to justify claims of superiority of breast milk over cow's milk, although, as will be pointed out, greater vigilance is required in the use of the latter, particularly during the first few weeks of life.

Some measure of the refinements of processing techniques made possible by standardization of feeding can be obtained from the following figures which indicate the availability (and competitive market) of proprietary products in 1952:[1]

500 (approximately) different brands of evaporated milk
24 different companies manufacturing 58 different milk foods
27 separate carbohydrate modifiers

Such a great abundance of preparations from which to choose can only be a tribute to the fact that, generally speaking, the problems of infant feeding have been solved. As Brenneman observed, "we have emerged from the chaos of complexity to the chaos of simplicity." The more or less feverish pitch with which proprietary firms promote their products usually depends on some more or less fastidious refinement of a basic pattern which serves all similar products. A recent trend which is spreading rapidly in popularity is the promotion of what Dr. Lee Forrest Hill calls the "one-formula

products," that is, those preparations which require only the addition of water to supply a complete formula containing twenty calories to the ounce, and usually simulating the composition of breast milk. Such preparations possess the advantage of ease of preparation and standardization and thus represent a further step in simplification of feeding. Furthermore, they have been widely and successfully used. The chief disadvantages are expense, lack of adjustability to individual needs and, above all, the fact that such "shotgun" or packaged mixtures do not test or exercise the thinking and knowledge of the physician who prescribes them.

An additional index of the great advancements which have been made is the fact that the basic needs and supplies have been so well worked out that a great deal of *faddism* characterizes modern feeding techniques. The age which solid foods are first fed is a good example:

35 years ago—solids were added continuously during the latter part of the first year.
25 years ago—under the influence of Marriott, addition of solid foods by the age of six months was advised.
15 years ago—it gradually became customary to add solids at least by three months of age.
Now—the average age of first feeding of solids is probably two months, but it is not unusual to see solids regularly started within the first week or to read where physicians boastfully report the successful addition of cereals, fruits, vegetables and meat within the first four weeks of life.

Although there can be little question that introduction of solids is occasionally indicated, there is likewise little question that no nutritional or psychologic advantage to the infant derives from the introduction of solid foods before the second or third month of life.[2,3] In this connection, it is also apparent that there is a widespread tendency to overfeed with milk mixtures that are too potent in calories. There are circumstances when more than 20 cal./oz. are required, but they are few and, as will be emphasized later, mixtures containing 20 cal./oz. provide an optimum water intake while providing adequate protein and calories. Finally, an even more striking example of faddism is the growing popularity of feeding an infant entirely by cup.

Such accomplishments only demonstrate, as do so many reports in medicine, what one "can get away with." They are usually motivated by the desire for "bigger and better babies," but it should be remembered that gain in weight is not necessarily the best criterion of optimum health in a baby.[4]

Another and perhaps more serious manifestation of refinement in feeding is the promotion of a wide variety of growth-stimulating substances and the alacrity with which proprietary companies pounce on any evidence, however meager, that a particular substance stimulates appetite or growth as an excuse for immediate production and intensive promotion. Various and highly expensive combinations of tranquilizers, vitamins, hormones, aminoacids and minerals result. Notwithstanding the immense indebtedness of American medicine to the remarkable achievements of the pharmaceutical industry, it behooves every physician to scrutinize carefully each product brought to his attention.[5] Table I summarizes some of the undesirable trends in infant feeding.

Thus, the simplicity of feeding today, so astonishing in comparison to the not too distant past, finds expression in the great variety of products available and regimens used. The wide margin of safety attests to the basic foundation of principles of infant feeding and, of course, to the capacity of the human infant to adjust to wide variations. It also makes possible the fact that faddism in feeding has not proved more harmful than it has. Dr. L. Emmet Holt has expressed the modern challenge in infant feeding as follows:[6,7]

1. Having placed infant nutrition on a sound basis, we are now striving for perfection, not just success.
2. Although we have mastered nutrition in health, nutrition under stress of disease is another matter. Frequently, a regimen which is quite satisfactory for a well baby may impose a handicap to a sick baby if it is not suitably altered. Perfection in the understanding of feeding normal babies will aid in the management of sick babies.

Prenatal Factors

Any campaign to understand and improve nutrition of infancy should begin with the study of the prenatal period. Nutritionally, an infant is nine months old at birth. The diet and general health status of the pregnant woman is highly important to the nutritional status and requirements of the neonate. This is particularly true of the premature infant and of multiple births. The very rapid growth of the fetus during the last trimester of pregnancy is well known and the major (approximately two-thirds of the total) storage of such critically important substances as nitrogen, calcium, phosphorus and iron occurs during this period.

Calcium and phosphorus retentions tend to be rather poor after birth,[8] and in the case of prematures, stores of these minerals are so inadequate and

requirement for rapid growth so great that the tendency for rickets can only be avoided by early provision of vitamin D within the first two weeks, particularly in infants fed breast milk. The importance of adequate vitamin D and calcium intake of the mother in this connection becomes especially apparent.

Likewise, the iron content of the fetus at birth depends on maternal intake and will be dangerously low in premature births. Whereas there is no real agreement as to when iron supplementation should be begun in such instances, early provision, perhaps by the end of the neonatal period, is important to make iron available when the infant needs it later (at about 100 days) when erythropoietic activity returns.[9]

It is no longer customary to give vitamin K to the pregnant woman for several days prior to delivery or by injection just before delivery, although the prothrombin level of the newborn can be elevated by this means, and it has been suggested that vascular integrity is also strengthened. Poor maternal diet exaggerates the neonatal drop in prothrombin level. The administration of vitamin K to the newborn has been stated to be ineffective in the prevention of hemorrhagic disease.[10,11] Recent extensive and well controlled studies indicate that vitamin K given to the mother or to the infant after birth is of definite value in the prevention of mortality due to hemorrhagic disease.[12] Plum has estimated that in Sweden, with 100,000 full-term births each year, 150 infant deaths from hemorrhagic disease are prevented by the prophylactic administration of 1 mg. of vitamin K to the neonate.[12] This estimate was based on observations in 17,740 infants who did not receive vitamin K and 13,250 who did.

Caution in the dosage used in the infant is dictated by the well-documented toxicity of synthetic analogues of vitamin K on red blood cells, causing hemolysis and hyperbilirubinemia,[13,14] particularly in premature infants. Many cases of kernicterus have been described. This iatrogenic complication results from use of excessively large doses of this vitamin, despite the early demonstration that very small amounts are required. Recently, it has also been reported that large amounts of vitamin K analogue given parenterally to the mother prior to delivery causes marked hyperbilirubinemia in premature infants within the first forty to seventy-two hours of life.[15] It is recommended that no more than 1 mg. vitamin K (for example, Synkavite®) be given routinely by intramuscular injection to the newly born infant.

Time of First Feedings

Certain aspects of the first few days of life deserve special mention. As is true of all mammals, heat production is relatively very low immediately after birth in comparison to later infancy (one-half or less), in relation to body surface. Consequently, calorie and water requirements are likewise low during this period. In addition, newborn infants, especially prematures, possess an enlarged extracellular space (excess sodium and water), the loss of which accounts largely for the physiologic weight loss. When one considers these facts, it is clear that there need be no compulsion regarding early feeding of newborn infants. Indeed, nothing need be given for the first forty-eight hours or so, if there is an indication for allowing a baby complete rest, as there frequently is following traumatic labor or delivery. In this connection, knowing the tendency toward respiratory complications in the premature, a certain delay in feeding is advisable. Also, breast feeding can be given a better trial if there is no urgency or compulsion regarding early provision of full strength feedings for the first few days. Dr. Clement Smith has aptly observed that more mistakes are made by feeding the infant too much or too early than too little or too late.

Renal Handicaps Affecting Nutrition

A great deal of attention has recently been focused on the important relationship between the limitations of renal function in infants and the desirable composition of artificial milk mixtures. These limitations are much more pronounced and important during the neonatal period than during later infancy.

Long before much was known about physiology of the newborn, it had been deduced on empirical and teleological grounds (at least by early 1800's) that cow's milk required modification in order to be "humanized." It gradually became accepted that cow's milk could best be adapted for use in human infants by the steps of alteration of protein (heat, acidification), dilution and addition of carbohydrate. The striking advances in processing and packaging during the past several decades soon made it apparent that the vast majority of infants could tolerate undiluted, unsweetened cow's milk or evaporated milk mixed with equal amounts of water. The use of such feedings spread and led, in

turn, to the frequent use of "super" formulas high in caloric, protein and carbohydrate content. Again, with the passage of time, it has become apparent that although there are indeed exceptions, there is little advantage to the use of "souped-up" formulas and, during the neonatal period, there are distinct disadvantages. As has been pointed out, weight gain has serious limitations as a criterion for optimal growth.

TABLE II. COMPOSITION OF MILKS

(After Gamble[14])

HUMAN MILK: total solids 12.5 gm/100 ml			
Fat	28%	Energy	88%
Sugar	60%		
Protein	10%	Structure	12%
Salts	2%		
COW'S MILK: total solids 13.0 gm/100 ml			
Fat	31%	Energy	67%
Sugar	36%		
Protein	27%	Structure	33%
Salts	6%		

One of the best rather early analyses of the nutritional qualities of human and cow's milk is a report of Dr. J. L. Gamble many years ago.[16] He divided food requirements into requirement for energy and requirement for structural materials. From Table II, it can be seen that, although both milks have essentially the same total solids content, cow's milk has three times as much structural material and 25 per cent less energy. He pointed out the logic of reducing excessive intake of structural material and increasing energy by the process of dilution and addition of carbohydrate. At the time, it was still believed that cow's milk protein was inferior to human protein, and dilution of protein to levels approaching that of human milk was not advised. Dr. Gamble also predicted that the large mineral load in cow's milk would bear worrying about.

In recent years, progress in understanding of renal limitations (particularly during the newborn period) has been largely responsible for re-establishing the advisability of an old procedure in accordance with new evidence:

1. Dilute cow's milk to reduce mineral content.
2. Add carbohydrate to fortify energy content and spare protein.
3. Serve in concentration similar to that of breast milk (20 cal./oz. or 100 cal./150 ml.)

Table III summarizes the important renal handicaps of the newborn:[17-20]

1. Glomerular clearance of electrolytes (for example sodium, chlorine, urea, phosphates and organic acid) is reduced to about one-third to one-fifth adult values on basis of surface area. This accounts for the strong tendency to retain sodium and water. The retention of chlorides and organic acids may contribute to acidosis. Excessive protein intake also predisposes to acidosis by increasing anion load (sulfates and phosphates).

2. Tubular reabsorption of water is sharply limited during the newborn period, resulting in relative inability to concentrate urine. This plus decreased glomerular clearances results in the production of a dilute urine. Twice as much water is required to excrete solute in an infant as compared to an adult (1.4 to 2.0 ml./mOsm as compared to 0.7 ml./mOsm). The feeding of a formula with high protein and mineral content consequently increases greatly the need or demand for urine water to excrete the great osmolar load. Unmodified mixtures can increase solute load as much as 85 per cent and renal water requirement by 100 per cent. Because solutes claim water for urinary excretion, extrarenal losses of water cannot be met by appropriate renal concentrations and water balance becomes precarious, with a tendency for hyperosmolarity and heat prostration.

3. Tubular recovery of base and manufacture of ammonia are also inadequate. High protein loads are also acid loads and the tendency to acidosis is thus further aggravated.

TABLE III. RENAL HANDICAPS AFFECTING NUTRITION

Glomerular	decreased filtration decreased mineral clearance tendency retention electrolytes (Na) & H_2O
Tubular	decreased water reabsorption inability to concentrate 700 = over 700 mOsm/L tendency to dehydration poor recovery of base tendency acidosis

Renal water requirement high (NB twice older infant)
Intolerance to solute and/or water load

Thus, whereas the normal infant can adapt to wide variations in protein, fat and carbohydrate content of mixtures, the infant fed unmodified cow's milk under stress of increased extrarenal water loss (high environmental temperature, fever, gastrointestinal upset, decreased intake) cannot conserve water because, as a result of the mineral content of "straight" cow's milk, the kidneys are already operating at approximately maximum capacity for tubular reabsorption or urinary concentration. In order to protect the occasional infant with such a problem, that is to buttress his adaptability to dehydration hazards, all neonates, especially, should be provided a mixture which will satisfy not only protein and caloric needs and appetite, but will also provide a low osmolar load which will spare renal water. These needs are met by a standard one to two dilution of evaporated milk with water and the addition of 5 per cent carbohydrate by weight. They are also met by several of the "one-formula" products available. Such mixtures provide more than ample provision of protein.

Because all of the described limitations of renal function are most pronounced in the immediate

postnatal state, the wisdom of providing a low calorie, low electrolyte fluid is apparent. The tradition of using a very dilute mixture for the first several feedings is thus substantiated.

Neonatal Tetany

This complex disorder is directly related to limitation of renal function in the neonate. It occurs with variable frequency during the first few days or weeks of life. Although classically characterized chiefly by convulsions, the clinical picture also consists of irritability, hypertonicity, colic, twitching, carpopedal spasm and laryngospasm. It is due to a combination of factors which result in hypocalcemia (usually below 8 mg. per cent or 4 mEq/L).

It has long been known that hypocalcemia frequently occurs in newborn infants, both premature and term. The level is lower and fluctuates more widely in prematures than in term infants.[21] In recent years, evidence has accumulated which indicates that hypocalcemia commonly occurs during the first day of life, frequently associated with "typical" tetany, and that there is a direct association with complications of pregnancy, labor and delivery, implying an influence of "stress" on calcium metabolism.[21,22] Such maternal complications or stresses as prematurity, diabetes mellitus, caesarean section, breech delivery, toxemia were associated with hypocalcemia on the first day of life. In addition, a particular syndrome of pronounced neuromuscular irritability associated with hypocalcemia has been reported in a number of infants, both premature and term, born of complicated pregnancy, labor or delivery.[23]

TABLE IV. MINERAL CONTENT OF HUMAN AND COW'S MILK
(National Research Council, 1953)

	Human mg./100 ml.	Cow's mg./100 ml.
Total minerals	210	720
Calcium	33	125
Phosphorus	15	96
Ca:P	2.2	1.3

The usual or "typical" case of neonatal tetany does not occur during the first few days of life and occurs particularly in infants fed cow's milk. Four factors are apparently involved: (1) reduced renal clearance of phosphorus, (2) high phosphorus load of cow's milk, (3) probable transitory hypoparathyroidism, and (4) some predisposing factor such as unusually pronounced renal handicap, prematurity, etc.

As can be seen from Table IV, cow's milk contains over three times as many minerals, four times as much calcium, and six times as much phosphorus as does human milk. The excessive phosphorus content and reduced Ca:P ratio tend to disturb the reciprocal relationships between calcium and phosphorus with resultant tendency to hypocalcemia and convulsions. Table V summarizes the mechanisms involved and the sequence of changes which result in tetany. The tendency for hyperphosphotemia due to loading is sharply accentuated by the previously described reduced glomerular clearance. In addition, it appears that transitory, "physiologic" hypoparathyroidism further influences the development of hyperphosphotemia and hypocalcemia. Histologically, the parathyroid glands of the neonate apparently are normal from immediately after birth to approximately seventy-two hours;[26,27] after this time the picture is usually one of hyperplasia,[26-28] particularly in those infants fed cow's milk preparation. This hyperplasia represents a compensatory reaction to the phosphorus load and although it has been shown that an increased phosphorus excretion occurs,[25] the reaction is inadequate to produce a fall in the serum phosphorus[27,29] and has been termed "inadequate compensatory hyperplasia."[30]

TABLE V. MECHANISMS INVOLVED IN NEONATAL TETANY
(After Barnett[25])

High phosphorus intake—all infants on cow's milk
Low phosphorus excretion
- Low glomerular filtration rate
- Transitory hypoparathyroidism

Elevation of serum phosphorus
Reciprocal lowering of serum calcium
Tetany—in some infants
- "Stress factors"

The reciprocal lowering of calcium would then tend to produce tetany in only a certain proportion of infants, apparently those subject to predisposing factors such as prematurity, diabetic mother, stressful labor, *et cetera.* Awareness of the broad spectrum of clinical signs of hypocalcemic tetany will alert the physician to early recognition and therapy. In this connection, the diagnosis of neonatal tetany, especially if occurring very early after birth, should arouse suspicion of maternal hyperparathyroidism. Several instances of this association have been reported and the retrospective diagnosis of maternal hyperparathyroidism made possible.[29,31-33]

Treatment involves reduction of the phosphorus load, usually by formula dilution, and the administration of calcium salts intravenously and/or orally. Dilution of cow's milk does not alter the Ca:P ratio but it does reduce the phosphorus load which may then be more adequately handled by the kidney. Cow's milk diluted 1:2 with water

plus 10 per cent carbohydrate would be a suitable formula and, with added calcium gluconate, has been recommended for routine use during the first week or so of life, where breast feeding is not possible.[33]

Vitamins

Attention has already been directed to the fact that present-day infant feeding owes much of its success to the increased understanding of vitamins. Needless to say, progress in the study of these substances continues daily. However, the profusion of available commercial preparations with an apparently infinite variety of composition, and the frenetic promotion to which both the laity and the medical profession fall prey, result in wastefulness which is not only unscientific but occasionally deleterious. Although supplementation of the diet with certain vitamins is essential during especially the neonatal period and infancy, there seems little doubt that the packaging of vitamins available for common use makes it difficult not to supplement with too many vitamins and/or too much of certain ones.

Vitamin C is usually prescribed within the first week in amounts of 30-50 mg. daily to all newborns, although the former figure is closer to the actual requirement.[35] Supplementation is not strictly necessary in breast-fed infants of well-fed mothers, but is probably advisable. Breast milk contains about 50 mg. vitamin C per 1000 ml., whereas cow's milk contains less than one-third of this amount. In addition to its importance in the prevention of megaloblastosis and scurvy, ascorbic acid is needed in the premature infant and in some term newborns to permit complete metabolism of certain amino-acids, especially phenylalanine, an essential amino acid.[36] Because of variations in quality of orange juice and frequency of poor tolerance, the use of orange juice has largely been replaced by ascorbic acid as included in polyvitamin preparations. In this connection, a recent report indicates that dilution of vitamin C with boiling water exerts no harmful effect on vitamin C content and boiling results in loss of only 25 per cent of the vitamin C-containing substances.[37] The incidence of scurvy appears to have increased during recent years.[37,38]

Vitamin D should be begun by the end of the first week because both human and cow's milk contain negligible quantities of this substance and because of the great demands of rapid growth and the tendency for low retention and consequent depletion of calcium after birth.[8] The amount of supplement recommended is 400 U.S.P. units daily for both breast-fed and artificially-fed neonates; premature infants should receive 1000 units as a daily supplement. Although there is considerable variation in individual tolerance to large doses of vitamin D, a daily intake above 1500 units in a normal infant will produce signs of toxicity such as anorexia, irritability, failure to thrive.[39] When one takes into account the widespread practice of fortification of foods, especially milk preparations and cereals, with vitamin D, the proclivity of the physician to prescribe and the mother to give, larger than necessary amounts of supplement can easily lead to overdosage. Very large intakes produce the typical clinical picture of hypervitaminosis D.[40] In other instances, unusual sensitivity to vitamin D, not necessarily given in excess, leads to a similar, self-limited syndrome which can supervene quite early in infancy.[41]

Vitamin A is also traditionally begun by the end of the first week, despite the fact that milk is fairly rich in this substance (human 1766 units/L, cow's 1133/L), and supplementation is not really necessary. The amount recommended is 1500 I.U. daily and should be continued at least for the first few weeks.

Vitamins of the B complex have always been considered to be adequately supplied in milk, and no supplement is required, certainly during the neonatal period. Thiamine is easily destroyed if excessive heating of the milk is carried out. Recently, a new syndrome was described and shown to be due to deficiency of pyridoxine (Vitamin B_6).[42] It consisted of increased irritability, "gastrointestinal distress," exaggerated startle response and convulsions. Although milk contains adequate amounts of this vitamin (human 110 gamma/L, cow's 480 gamma/L), it was discovered that the great majority of babies were receiving a proprietary liquid milk in which the pyridoxine had been reduced by heat. The resulting symptomatology, however, represented a marginal deficiency, since the full-blown picture of B_6 avitaminosis was not described. Because of this and because the incidence of convulsions in infants fed this milk preparation was actually quite low, it is probable that some predisposing factor(s)[43-46] must be present, namely:

1. Poor endowment from mother plus poor dietary supply.

2. Inherent need for higher intake of vitamin B_6 on the basis of "pyridoxine dependency" in infants whose mothers ingested large amounts of the vitamin during pregnancy.

3. Inherent need for higher intake of vitamin B_6 on the basis of an idiopathic metabolic aberration.

4. Reduced threshold to convulsions due to inherent factors or to reduction in magnesium and calcium retentions.

Thus, convulsions associated with need for administration of pyridoxine can occur during the neonatal period in both breast and bottle-fed babies, and not necessarily associated with the relative lack of pyridoxine in the milk ingested. Awareness of this possibility is of the greatest importance in the differential diagnosis of convulsions during early infancy because of relative simplicity of treatment. Because of occasional anomalous requirements, a dose of 5-10 mg. of pyridoxine hydrochloride should be given in therapeutic trial to any infant with convulsions of unknown etiology.

The actual optimum or recommended requirement for vitamin B_6 has not yet been securely established. The human infant is very sensitive to B_6 deficiency, since over forty enzyme systems are dependent on this vitamin. Exact requirement varies from patient to patient, but is at least 0.1 mg. daily on regimens providing maximal utilization. The usual evaporated milk mixture provides 0.2 to 0.3 mg. daily and this has been recommended as the minimum requirement for early infancy.[46] Perhaps a level of 1 mg. daily should be suggested, since the above figure does not represent a wide margin of safety.

Vitamin E requirements have not been established. It has been known for some time that the serum levels of these hormones are low at birth and increase rapidly in breast-fed and much less so in bottle-fed infants,[47] indicating poor placental but excellent mammary transfer. The recent work of Gordon and associates,[48-51] utilizing the erythrocyte hemolysis test in hydrogen peroxide, indicates a deficiency of tocopherol in newborn infants, both full-term and premature. There have been no clinical correlates of this laboratory evidence of deficiency, which is easily remedied by breast-feeding, less easily by whole cow's milk and not at all by skim milk. This evidence of vitamin E deficiency is particularly prominent in premature infants. They suggest that such infants may require daily supplementation in amount of 0.5 mg/kg. but reserve definite recommendation until positive clinical evidence of a deficiency state can be ascertained.

Amino Acids

Requirements for specific amino acids are gradually being established and little can be said here that is pertinent to the newborn infant. Mention should be made of the inadvisability, in the light of present knowledge, of the fortification of milk with lysine in order to promote increase in appetite and weight gain. There has been much to do about this, but it is apparent that such supplementation may actually be hazardous, since intake of a balanced mixture of amino acids is more important than fluctuations in individual amino acids.[52] The "band-wagon" enthusiasm with which several proprietary companies have peddled such supplements indicates how greatly the motive for profit can exceed the motive to profit.

Recently, several reports have demonstrated that the hereditary "inborn error of metabolism" known as phenylpyruvic acid oligophrenia can be significantly improved by eliminating phenylalanine from the diet.[53] The disorder occurs once in approximately every 25,000 births. Routine testing of the urine of newborns with 5 per cent ferric chloride to identify the phenylpyruvic acid has been instituted in many areas. The test can also be performed on a diaper. The test may not become positive until the end of the first month, and will therefore have to be repeated if the index of suspicion is high. A much simplified test has recently been described.[54] Awareness of this disorder represents an opportunity to remove one more specific entity from the large group of unknown causes of mental retardation.

Galactose Disease

This is a serious disease which manifests itself during the neonatal period and which, if identified early, can be completely prevented by eliminating galactose from the diet. It is a hereditary disorder caused by an inborn error of metabolism which causes an inability to metabolize galactose normally and results in a spectrum of signs and symptoms among which are persistent jaundice, vomiting, diarrhea, hepatosplenomegaly, cirrhosis, cataracts, renal damage and mental retardation.[55] Suspicion will lead to testing the urine for reducing substance; glucosuria and diabetes mellitus can be eliminated by use of glucose oxidase which has been incorporated in indicator papers

(for example Tes-tape®) and which identifies glucose only.

Essential Fatty Acids

Hansen and associates have recently reported a series of experiments with the extended feeding of diets extremely low in fat to healthy neonates.[56-59] It was found that spontaneous caloric intake was sharply increased in order to maintain weight gain of control infants. The addition of linoleic acid resulted in 20 to 40 per cent reduction in caloric intake, but in an unchanged growth curve, indicating indirectly that deficiency of linoleic acid elevates the basal metabolic rate in infants as it has long been known to do in a variety of experimental animals. The increased ratio of caloric intake/weight gain thus induced not only results in inefficient caloric utilization, but in an increased solute load as well. In addition to the increased caloric requirement, the following signs and symptoms were noted in these infants: frequent large stools, perianal irritation, dermatitis (especially in the Negro infant). These were likewise reversible with the addition of linoleic acid. It was concluded that these manifestations were prevented when the diet contained at least 1 per cent of the calories as linoleic acid, as is provided by the usual evaporated milk formulas. An intake of 4 per cent of the calories as lineolic acid was considered optimum for the healthy young infant.

This evidence should do much to diminish the feeding of low-fat milk mixtures to young infants, both term and premature. Although it is true that premature infants assimilate cow's milk fat less well than term infants, it is also apparent that the great majority of these infants tolerate very well a large number of full-fat evaporated milk preparations and that full-fat feedings result in retention and assimilation of the fat, although a significant proportion is lost in the stool.[60] Also, there are several proprietary preparations of cow's milk in which the butterfat has been replaced with more readily assimilable and more highly unsaturated vegetable oils.

Conclusion

The specialized nutritional requirements of the neonate are directly related to the physiologic and metabolic immaturity which characterizes his developmental status and to the handicaps thus imposed during the process of postnatal adaptation. These handicaps become more threatening under the burden of perinatal stress factors, including prematurity, caesarean section, diabetic mother, breech delivery. In addition, these special considerations must subserve the demands for rapid growth.

Improved knowledge about the infant and his needs makes it abundantly clear that breast feeding is the ideal regimen for a neonate. Failing that, the simplest artificial feeding regimen employing the principle of humanization of cow's milk should be instituted in order to contend with the special problems incident to the composition of cow's milk and the immature renal function of the neonate. Vitamin supplementation is essential only for C and D, optional for A and unnecessary for members of the B complex, except in special circumstances. Vitamin K, 1 mg., should be given at the time of birth. Vitamin E may be required for the premature infant. There is no virtue in the routine introduction of solid foods before two to three months. "Special" vitamins and additives to stimulate appetite and growth should be avoided. Convulsions due to B_6 deficiency, onset of phenylpyruvic oligophrenia and galactosemia may occur during the neonatal period and early identification depends on heightened awareness. The importance of essential fatty acids in infant feeding is becoming increasingly apparent.

Villous Papillomas of the Rectum

A Review of Twenty-five Cases

● *Villous papillomas of the rectum and lower colon deserve consideration as distinctly different from the much more common adenocarcinomas and "benign" polyps of the colon.*

WILLIAM T. SMITH, M.D.
Minneapolis, Minnesota

Dr. Smith is Clinical Instructor in Surgery, University of Minnesota Medical School.

Presented before the Minneapolis Surgical Society, May 1, 1958.

A BRITISH pathologist, Holmes, originated the term "villous papilloma" to distinguish it from the adenomatous type of polyp. This is a particularly useful classification for the clinician which allows him to consider the tumor as a separate entity, different from adenocarcinoma and the adenomatous polyp. The origin, characteristics, and potentiality of these tumors differ from other tumors of the colon. The characteristic difference between villous papillomas and ordinary adenomas is that the former are soft, velvety and impart to the examining finger the feeling of soft jelly. They are so soft, spongy and friable that it is not unusual to shear off a piece of the tumor during performance of a proctoscopic examination.

The mucosa surrounding the tumor may seem normal. On careful scrutiny, however, tiny papillations will be discovered which on microscopic examination can be identified as tiny, gross tumors. These papillations must be removed or destroyed with the tumor or recurrence is almost inevitable. The existence of this zone of tiny tumors is a strong argument in favor of prolonged follow-up study after treatment is completed.

(Turn to Page 107)

According to Dukes, villous papillomas are the end result of a growth pattern which affects mainly the superficial epithelium in contrast to the adenoma which is the result of a growth pattern affecting mainly cells of the deeper layers; increased muco-epithelial surface other than the glandular elements of the villous configuration tends to support this theory. Unlike ordinary adenomas, villous adenomas are seldom pedunculated. Usually they have a broad base and are fungating. The surface is wet and covered with a glairy mucus. The tumor is usually attached to the muscular layer of the bowel, unless invasive carcinoma is present. Villous tumors have a decided tendency to undergo changes characteristic of malignancy which usually is of low grade. Invasion takes place slowly and metastases occur late; usually spread occurs by direct invasion instead of by invasion of lymphatics, vascular, and nerve channels. Invasive carcinoma is observed in at least one out of ten tumors. This change to malignancy is almost always accompanied by alteration of the consistency of the tumor and a firm plaque or nodule is usually palpable. Thus, areas of induration or ulceration in villous tumors usually indicate malignant change.

Age

Villous papillomas are seldom seen in patients younger than forty years of age. The average age in Bacon's series is fifty-five years and in Sutherlands it is sixty-five years. Experience of others reveals that villous tumors are found more commonly in the older age groups.

Symptoms

The most common symptom is discharge from the rectum of large amounts of mucus stained with blood. Tenesmus and a feeling of incomplete evacuation are common and occasionally external prolapse, which may be mistaken for a prolapsed hemorrhoid, has been reported. It is quite significant that in cases of villous tumor of the rectum, signs and symptoms may be present for years, in contradistinction to most tumors of the bowel which undergo malignant change. This places emphasis on the benign nature of villous tumors. Villous papillomas are rare tumors. Until the turn of the century, few authors reported more than one or two such lesions in many years of surgical practice. Recently, larger series are being reported. Twenty-five villous papillomas have come under my observation since 1950. The youngest of my patients was thirty-five years and the oldest eighty-six—the average being sixty-six years. All of these tumors were discovered during proctoscopic examination, either in the rectum or the lower segment of the sigmoid. The size of the tumor varied from those which involved almost the entire circumference of the bowel to lesions 2 or 3 cm. in diameter.

Treatment

When surgery is under consideration, the actual bulk of the body of the tumor is unimportant. The extent of the attachment of the pedicle, or base, is the significant factor. Usually when the area of attachment involves half or less than half the circumference of the bowel lumen, excision *en masse* or fulguration can be accomplished. For the purpose of diagnosis, simple biopsy was worthless in nearly all of my cases. Specimens of tissue removed in this manner was invariably reported as benign. Tumors must be removed *en masse* and very carefully examined microscopically if one hopes to discover evidence of carcinoma. The pathologist's report, based on this study of bits of tissue removed from various parts of the tumor, was worthless. Of the twenty-five tumors thus observed, all but four were removed through the rectal outlet for total microscopic examination. In three of the four cases where the tumor was not removed in this manner, anterior resection and primary anastomosis were done. In these cases the tumor was not removed through the rectal outlet because the tumor was either situated too high or was too large. Because of the age of one patient, the tumor was destroyed by fulguration alone. Two of the tumors removed by anterior resection showed invasive carcinoma. Both occurred in young patients and both recurred one and three years after operation, respectively. Both patients have since died. Of the twenty-one tumors treated from below, twelve could be grasped through the dilated anal canal and excised *in toto*. Great care was taken to excise the tumor, including a margin of one-fourth to one-half inch of normal mucous membrane around it. If papillations remained, they were destroyed by fulguration. One tumor in a forty-seven-year-old white woman removed in this manner contained invasive carcinoma and abdomino-perineal resection was performed subsequently. The remaining eight tumors

were too bulky or too high in the rectum to adequately excise through the dilated anal canal. To facilitate exposure of the tumor, a posterior proctotomy was performed by splitting the anal sphincter muscles in the midline posteriorly and continuing the incision cephalad along the rectal wall. When necessary, the coccyx was excised. This allowed the entire rectum to be laid open and provided adequate room for excision of the lesion. Following resection of the tumor, the incision was carefully closed with chromic catgut. These incisions all healed primarily and no incontinence has resulted. Each of the eight patients was prepared carefully preoperatively with administration of Neomycin and Sulfasuxidine. Sulfasuxidine was given in dosages of 12 gm. daily for five days before the surgery and the Neomycin was given in dosages of 500 mg. every four hours, two days prior to surgery. At least two of the three patients had been told elsewhere that abdomino-perineal resection was necessary in their case. In three of the cases where tumors were removed from below, the pathologist reported invasive carcinoma in one, carcinoma *in situ* in two. One tumor showed invasive carcinoma and, as has been mentioned, was treated by abdomino-perineal resection. The other showed carcinoma *in situ* in only isolated foci of malignant change. This was not considered an indication for radical surgery. In one of those cases where actual carcinoma was found, radical surgery was employed. The patients who had tumors removed from below had been carefully followed by frequent proctoscopic examination. Wherever there was evidence of recurrence, tissue was carefully biopsied and the base thoroughly fulgurated. All have done well over a period of seven years. No treatment other than fulguration has been necessary. The only complication encountered was a slight stricture of the rectal ampulla where large amounts of tissue had been removed. Three patients developed contracture postoperatively but in each instance, this caused relatively little disability and responded to local dilatation.

Summary

In reviewing these twenty-five cases of villous papilloma, I wish to emphasize that villous papilloma should be regarded as malignant until proven otherwise. The only acceptable diagnosis of these lesions is one made by the pathologist's scrutiny of serial sections of the entire tumor. Carcinoma *in situ* is not included among those tumors which require radical surgery. Invasive carcinoma in a villous tumor must be treated as frank adenocarcinoma. This tumor may appear quite large and bulky and seems to present a serious problem on proctoscopic-anoscopic examination. By careful study, however, the base of the tumor may be found to involve only one-half or less of the circumference of the rectum and often it is not too difficult to excise such tumors from below. The conscientious surgeons should make every effort to eradicate these tumors by local means, resorting to radical surgery only upon necessity. It is not fair for the surgeon to assume that a tumor is malignant and subject his patient to abdomino-perineal resection until it is proved that invasive carcinoma is present. Unfortunately, in too many instances patients are treated by abdomino-perineal resection only to learn subsequently that examination of the tumor reveals, at worst, only isolated foci of non-invasive carcinoma.

TUBERCULOSIS DEATH RATES, BY STATE AND TERRITORY, 1957

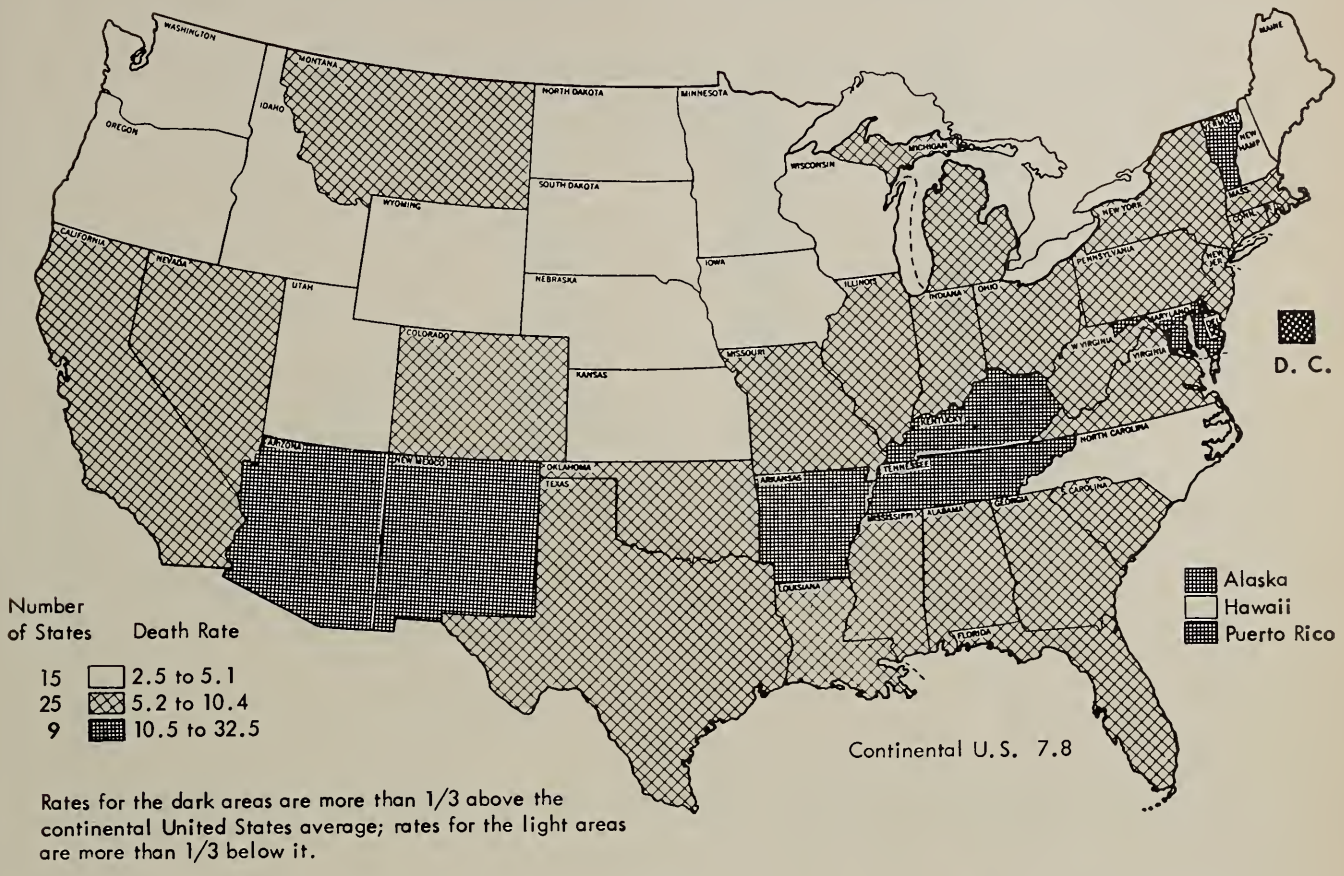

Fig. 1.

The Tuberculosis Problem Now

A Broad Perspective

FLOYD M. FELDMANN, M.D.
New York, New York

Presented at the Minnesota Public Health Conference, Minneapolis, Minnesota, September 25, 1959.
Dr. Feldmann is Director of Research of the National Tuberculosis Association.

TO THOSE FROM the rural areas of Minnesota, where tuberculosis rates are lower than was thought possible twenty years ago, the extent of this disease problem and the difficulties in planning efficient control measures may come as a surprise. The estimated figure for tuberculosis deaths in 1958 is 12,070. The number of reported cases for the same year was 83,400, of which 63,300 were active or probably active.

The statisticians of the Public Health Service and the National Tuberculosis Association estimated that in 1956 there were 250,000 active cases in the country, 150,000 of whom were known, and

that there were in addition 550,000 inactive cases in need of supervision. It was also estimated that there were 1,200,000 persons who had once had tuberculosis. This gives a grand total of 2,000,000 who have or have had tuberculosis. With fewer deaths in recent years in relation to new cases, there is some doubt that this total is decreasing very much.

RATES BY AGE, NEWLY REPORTED ACTIVE* TUBERCULOSIS CASES AND DEATHS
UNITED STATES, 1957

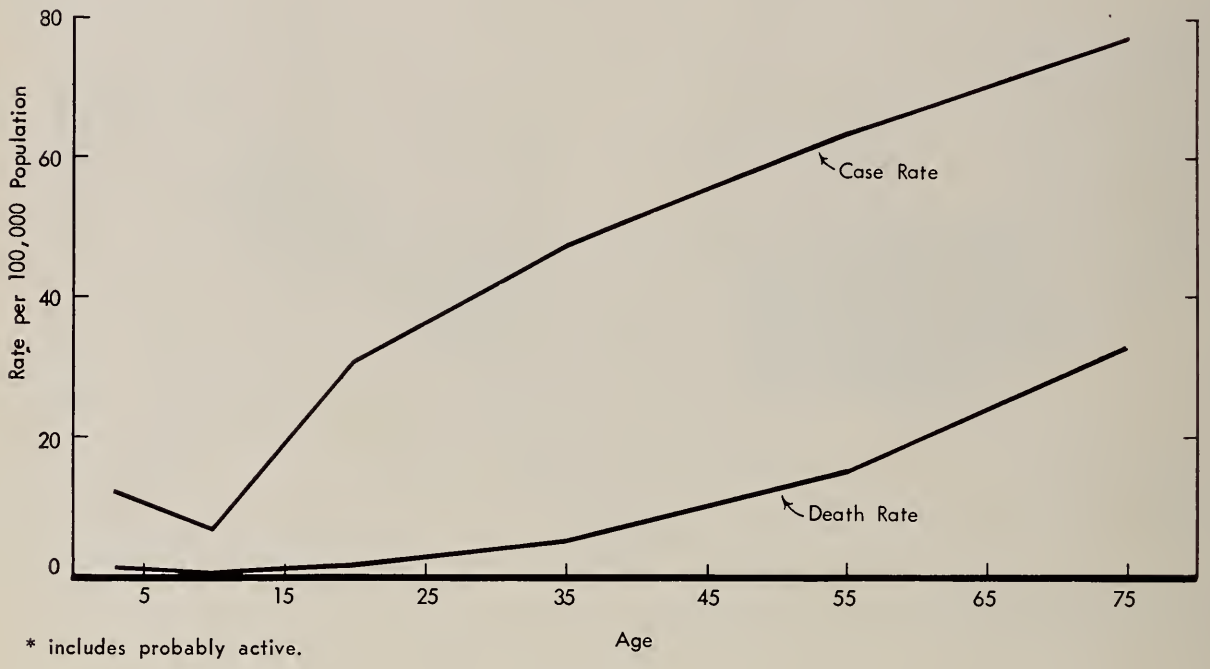

Fig. 2.

Compared with the figures of even ten years ago, these numbers seem small, but compared with those of other communicable diseases, they are still of first importance. Tuberculosis accounts for about as many deaths as all other infections and parasitic diseases combined.

The amount of money spent for tuberculosis control in this country has been increasing in recent years. The Public Health Service estimate for 1956, covering hospitalization and rehabilitation, compensation and public health measures for control, was $725,052,000. The comparable figure for 1952 was $621,023,000.

In years gone by, the situation was essentially a continuous emergency epidemic, and little attention was given to more precise evaluation of the problem in terms of individualized control methods. But now more individualized control is necessary to cut short a long period of rather slow progress.

To make a more direct attack on tuberculosis, we need to know where the disease is occurring, what kinds of people are suffering from it, how good our weapons are, and what trends are taking place. With this information, new strategy may be developed.

The disease is not uniformly distributed geographically. The current high mortality-rate area in this country is in the form of a band of states running from the Southwest to the mid-Atlantic section (Fig. 1). Incidentally, there is a close correlation between mortality, morbidity, and infection rates.

The geographic distribution can be narrowed still further by separating the urban and rural rates. In 1956, the death rate in cities of 500,000

population and over was 13.5, in cities of 100,000 and over it was 10.3, and in the rest of the country it was 6.8. In large cities the tuberculosis problem is highly concentrated in a few wards.

year the whole curve moves down to a lower level. The fifty-year-old people were subject to the fifty-year-old rate in 1957. In 1967, when they will be sixty years old, the point on the curve for the

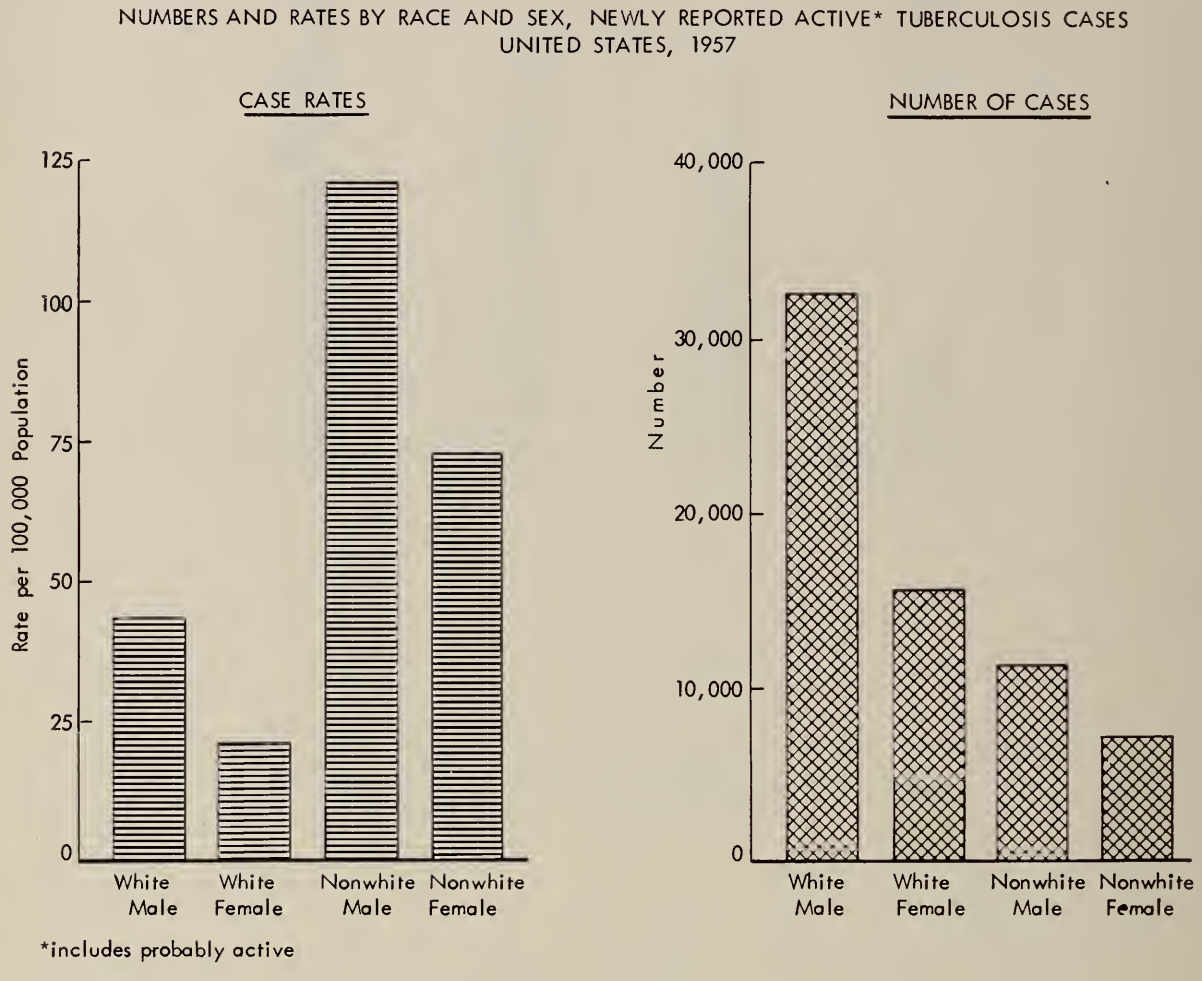

Fig. 5.

Knowing where the disease is most prevalent does not help much unless more information is available about the kinds of people likely to be affected. Traditionally, morbidity and mortality rates have been tabulated on the basis of age, sex, marital status, and ethnic background.

In 1957, the gross death rate for all ages was 7.8 per 100,000, but the death rates were higher in the older age groups and reached a high of 32.8 in people over sixty-five years of age. Case rates were also at high levels in the older ages (Fig. 2).

Paradoxically, this does not mean that people have higher rates as they advance in age. Each sixty-year-old people will have moved down to a point lower than the 1956 point for fifty-year-old people, provided that present trends continue.

People of average age thirty-five had a rate of 75.1 in 1936 (black bar, Fig. 3). Twenty years later, at average age fifty-five, they had a rate of 16.6 in spite of an apparent upward progression with age in any particular year.

Up to age thirty there is a marked difference by race, but not by sex. After that, the male rates rise rapidly for both white and non-white, and the female rates tend to remain level until age sixty (Fig. 4). All these rates are falling, the female rates faster than the male rates for both

white and non-white, so these differences by sex will likely be greater as time goes on.

Here again is something of a paradox in the difference between rates and numbers. The non-whites have the highest rates, but there are more rate areas and groups must not be forgotten.

Fortunately, our tools have been steadily improved. With the drugs now at hand, plus surgery, a good therapeutic result can be expected in over 90 per cent of all patients who do not have ex-

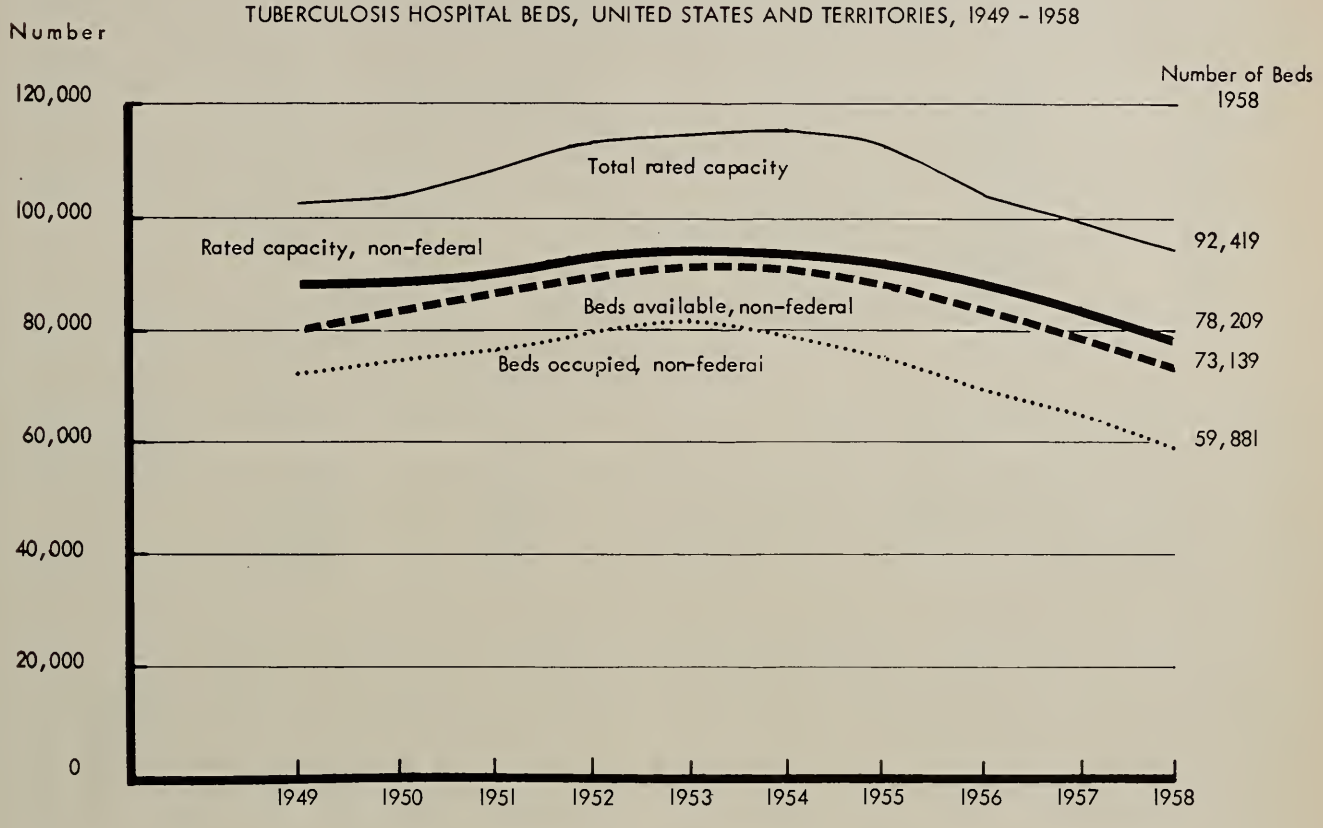

Fig. 6.

cases and deaths among the whites, simply because there are more white people (Fig. 5).

At this point one is tempted to conclude that tuberculosis is confined to a rather limited area of the country and to just a few segments of the population. The figures do indicate where and among whom the disease is more of a problem, but the distinction between rates and actual numbers must be kept in mind. For instance, even with the higher rates in older people, about half of all new cases occur among people under the age of forty-five. Cities of over 100,000 may have higher rates and actually account for 42 per cent of all deaths, but this means that 58 per cent of the deaths come from smaller cities and rural areas. Control efforts may be more efficient in high-rate areas, but the considerable number of cases in low-

tensive lung destruction and who receive a full continuous course of modern treatment. It should be noted that there are still only three major drugs in use, they must be given for long periods, and they do not eliminate all tubercle bacilli in the body. The disturbing facts are that over three-fourths of new patients have advanced disease and from 20 to 40 per cent do not receive adequate treatment. This results in treatment failures and relapses. Hospitals are now reporting that from 20 to 30 per cent of their admissions are retreatment cases. No one knows how many of these are treatment failures or how many are relapses. If we estimate that there are 250,000 active cases in the country and about 12,000 deaths a year, the fatality rate is about 4 per cent a year.

The number of admissions to hospitals is now

slowly declining, but the number of beds occupied has dropped a little more rapidly (Fig. 6). Until last year, most of the decrease in hospital bed occupancy was the result of shorter periods of hospital treatment rather than a fall in numbers of hospitalized patients. Total length of treatment per patient is probably not much shorter than in former years because drug therapy is usually continued for many months after discharge from a hospital. In most parts of the country, presumably, there are enough hospital beds.

TABLE I. TUBERCULOSIS DEATHS IN THE UNITED STATES

Year	Number	Decline
1946	50,911	3.8
1947	48,064	5.6
1948	43,833	8.8
1949	39,100	10.8
1950	33,959	13.1
1951	30,863	9.1
1952	24,621	20.2
1953	19,544	20.6
1954	16,392	16.1
1955	14,940	8.9
1956	14,061	5.9
1957	13,324	5.2
1958	12,070	(est) 9.4

The tools for case finding and diagnosis have undergone some changes in recent years but are still limited primarily to the x-ray, tuberculin test, and bacteriological examinations. It is generally recognized now that many other conditions can simulate tuberculosis on the x-ray, that tuberculin sensitivity and tuberculosis infections are not always synonymous, and that there are many strains of mycobacteria that look like tubercle bacilli under the microscope and can even cause a similar type of disease. But these developments have brought about better understanding as well as difficulties in interpretation.

The number of annual deaths has been decreasing rapidly in recent years (Table I). The year of greatest decline was 1953. The rates decreased from 15.8 in 1952 to 7.0 in 1958. The number of cases reported has been declining less regularly (Table II). The largest declines in both mortality and morbidity rates have taken place in the younger age ranges, as one would expect.

Basic to these trends are the changes taking place in the pattern of tuberculosis infection. Fortunately, too few infections have been taking place to maintain the disease, and a continuation of this deficit would lead eventually to its disappearance, but I hope we shall not wait years for this to take place.

Tuberculosis is no longer unpredictable. The relative rates of prevalence and incidence in major groups of the population are known. Furthermore, the risk is limited almost entirely to those now infected. Tuberculin test data, limited as they are, reveal that the rates of new infections are very low. In areas such as Minnesota, the rate is probably less than one new infection per thousand population per year. If low degrees of tuberculin sensitivity are discounted as insignificant, and this appears to be justified, the actual rates of infection are only about half those usually reported.

TABLE II. NEW ACTIVE CASES OF TUBERCULOSIS IN THE UNITED STATES

Year	Number	Per Cent Decline
1952	85,607	Activity not classified before 1952
1953	83,250	2.8
1954	78,592	5.6
1955	76,245	3.0
1956	68,866	9.7
1957	66,437	3.5
1958	63,336	4.7 (est)

From various tuberculin testing programs, it appears that there is a definite relationship between age and infection rates, and the curve for the population as a whole would look something like that in Figure 7. This is what one would expect from the case and death rates. But the risk of developing tuberculous disease, once infection has taken place, has quite a different relationship to age: high in infancy, low in the elementary school ages, and rising through the teen ages to a peak some place between ages twenty and thirty (Fig. 8). After age thirty, men appear to face more risk than women, but this may be due to a difference in infection rates.

Many other factors add to the risk. Previous active tuberculosis, contact with a tuberculous patient, diabetes, silicosis, weight below normal for height, alcoholism, low economic status, ethnic background other than white, limited education, size of tuberculin reaction, lack of family connections, any abnormality on the chest radiograph—all influence the probability of tuberculosis developing in the infected individual.

With the tuberculin test as the primary instrument, one should be able to sort out those who are

most likely to be the tuberculosis cases of the future and keep them under observation. Perhaps the new serum test will aid in further reducing the number to be watched. If prophylaxis through chemotherapy fulfills its promise, supervision could be cut short and new tuberculosis cases would become a rarity.

This would all be possible only as an extension of a good control program already in operation. I cannot emphasize too strongly the basic necessity for adequate individual supervision of known cases and the examination and follow-up of contacts. These are the groups with the highest risk. Some agency in the community must be doing this fundamental job in tuberculosis control if anything at all is to be accomplished. Beyond this, it should now be possible to extend the effort to gain a real strangle hold on tuberculosis.

Public Health Aspects of the

● *Doctors concerned with the care of pregnant women and of newborns will do well to read carefully* The Public Health Aspects of the Prematurely Born Infant. *More babies are born in Minnesota every year; simultaneously, prematurity and immaturity are on the increase. The newest criteria of prematurity are reviewed. More than half of the perinatal deaths each year are in premies. Physicians concerned with saving more babies must direct many co-operative efforts towards the management of the problems of the premature.*

THERE has been a continuing increase in the number of live births in Minnesota during the past two decades; from 50,118 in 1938 to 84,924 in 1958, a 69 per cent increase (Fig. 1). This increase has occurred throughout the United States with a national total of more than four million live births annually for the past five years. A continuing increase is anticipated in the foreseeable future, for the next decade or two. By 1970, it is expected that there will be six million annual live births. Along with the increased number of births, the percentage of hospital deliveries has also increased; from 43 per cent in 1933 to 62 per cent in 1938, to 99.4 per cent in 1958. Thus, only a few hundred babies are born each year outside of Minnesota hospitals. Hence, the necessity for continuing interest in adequate hospital facilities and services. It is of interest to note that 99.9 per cent of all births in Minnesota are attended by physicians.

Accompanying the tremendous increase in the number of live births there has been a continuous decrease in the infant mortality rate. In 1915 it was 70 per 1,000 live births; in 1938 it was 38.8; and in 1958 it was 23.1. This is a reduction of 67 per cent since 1915 and of 40 per cent since 1938 (Fig. 2).

The low point, however, was reached in 1956

Prematurely Born Infant

ALLYN G. BRIDGE, M.D.
EUNICE DAVIS, M.D.
Minneapolis, Minnesota

Presented at the Institute on Care of the Premature Infant for hospital and public health nurses, University of Minnesota Center for Continuation Study, November 30, 1959.

Doctor Rosenfield is director of the division of special services and acting chief of the section of maternal and child health, Doctors Bridge and Davis are pediatric consultants, Minnesota Department of Health.

with a rate of 21.9 per 1,000 live births. This was also the low point for the United States with a rate of 26.0. Thus, there was a slight increase in 1957 and 1958 in Minnesota as well as nationally. This is the first increase in the infant mortality rate in the United States in two decades and there is, therefore, considerable concern as to the cause of the increase as well as to the possibility of a continued rise in mortality. In Minnesota the rise in the mortality rate has been due almost entirely to an increased mortality from communicable diseases, and specifically from pneumonia of staphylococcal and viral infection.

The neonatal death rate (death of infants less than 28 days old) has also decreased, from 41.2 per 1,000 live births in 1915 to 26.2 in 1938, and to 17.5 in 1958. This is a reduction of 57.5 per cent since 1915 and of 33 per cent in the past two decades (Fig. 2); but the percentage of decrease has not been as great as that of infant mortality. In other words, we have been more successful in reducing deaths during the postnatal period (between one and twelve months of age) than during the first month of life. Therefore, if we are to further reduce infant deaths we must succeed in reducing the causes of death in the neonatal period, and particularly during the first few days after birth. Hence, our special interest

in this period of life. This is the reason for the current perinatal mortality study in Hennepin county, at Duluth and other areas in the state, and most recently in St. Paul and Ramsey county where such a study is now being developed.[2,3]

Prematurity (or immaturity) is a major factor in fetal deaths (stillbirths) and in deaths among babies during the neonatal period. More than half of the 138,000 annual deaths in the U. S. which occur in the perinatal period, extending from the twentieth week of pregnancy through the first week after birth, are among premature infants (those weighing 2,500 gm. [5½ lb.] or less at birth).[4,5] While this definition of prematurity of the World Health Organization has been approved by the U. S. Public Health Service and Children's Bureau, American Academy of Pediatrics, State Health Departments, The Association of State Maternal and Child Health Directors, the American Public Health Association, and other agencies it should be pointed out that it is not entirely satisfactory. A brief consideration of the many criteria proposed for the diagnosis of prematurity and their associated problems is of interest.

Prematurity is the termination of pregnancy in the period from the beginning of the twenty-eighth week to the thirty-seventh week of gestation. The usual estimate of a full-term pregnancy is 280 days (ten lunar months or forty weeks). While this estimate is used quite freely as a standard, it should be kept in mind that there are great variations, from 220 to 330 days, with an average of 270 days. Even if the exact date of conception is known, which is seldom, the calculated date may be off one to two weeks, early or late. The diagnosis of prematurity based on clinical signs depends on the training, experience, and clinical judgment of the physician. It varies from one physician to another and from time to time by the same physician. It is therefore neither objective nor standard.

Since a definition of prematurity based on calculation of the gestation period is not satisfactory, certain objective criteria have been adopted.[6] Such criteria as birth weight, crown-heel length, head and chest measurements, and the degree of development of certain centers of ossification are more objective than are clinical signs. Alone or in combination with one another or with gestational age, the criteria that indicate (or at least suggest) prematurity are:

1. Birth weight of 2500 grams (5½ lb.) or less
2. Crown-heel length of 47 cm. (18½ in.) or less
3. Occipito-frontal diameter of head 11.5 cm. (4½ in.) or less
4. Head circumference of less than 33 cm. (13 in.)

TABLE I.
TOTAL LIVE BIRTHS, FULL-TERM AND PREMATURE
(Minnesota, 1958)

Live Births	Number	Per Cent
Full-term	79,948	94.14
Premature	4,976	5.86
2001-2500 gm.	3,209(64.5%)	
1501-2000	973(19.5%)	
1001-1501	408(8.2%)	
Under 1000	386(7.8%)	
Total	84,924	100.00

5. Thorax circumference of less than 30 cm. (11¾ in.)
6. Disproportion between head and thorax of more than 3 cm.
7. X-ray evidence of development of centers of ossification

There are however, certain problems encountered in using these criteria. It is difficult to measure accurately a tiny squirming infant, and length varies greatly with weight. Other measurements are time-consuming. X-ray of ossification centers (usually the proximal tibial epiphysis) requires special techniques and trained personnel, is not readily available in the out-state areas, and is accurate only within wide limits. The single criterion of prematurity that has been most generally used is a birth weight of 2,500 gm. (5½ lb.) or less. The weight is easily obtained and, although not an exact indicator of prematurity, has provided a satisfactory criterion of the need for special care, as well as a uniform basis for statistical analysis. Some advocate the use of two of the three criteria of weight, length, and gestation.

The incidence of prematurity varies from 6 to 16 per cent. In the United States the incidence of premature birth is approximately 7 per cent of all live births in population groups of reasonably favorable socio-economic circumstances.[4] In Minnesota, the rate is 5.9 per cent (Table I). The incidence is higher than average among younger women (fifteen to nineteen years), among primiparas, and in women having their first child past age forty. The rate is higher for negro infants, in multiple births, and in women with a history of previous fetal loss. Lack of prenatal care, unfavorable socio-economic conditions, ma-

ternal dietary deficiencies, and certain obstetrical complications such as toxemia and abruptio placenta are also associated with a high rate of prematurity. However, the majority of premature births are not satisfactorily explained.

TABLE II. OBSTETRIC COMPLICATIONS BY INFANTS' BIRTH WEIGHT
Hennepin County Perinatal Mortality Study
(1710 Neonatal Deaths 1952-1956)

Complication	Weight of Infant in Grams					Premature Total	Full-Term	Total

Total	66	33	32	40	71	242

The five-year summary of the Hennepin County Perinatal Mortality Study for 1952-56[2] shows that obstetric complications were encountered in 747 of the 1710 infants in the study, or 44 per cent of the neonatal deaths (Table II). Thus, in more than half of the pregnancies there were no known obstetrical or maternal abnormalities; 614 out of the 747 complications occurred in premature births, mostly abruptio placenta, placenta previa, undiagnosed types of antenatal bleeding, and toxemia.

Fetal deaths are also associated with maternal factors. Of 255 fetal deaths studied by the committee in 1955, maternal factors were found in 242 with 70 per cent occurring in premature births (Table III). A history of previous premature birth or previous abortion occurred in 36 per cent of the premature fetal deaths. Obstetric complications were mostly toxemia, abruptio placenta, antenatal bleeding of unknown cause, and prolapsed cord. One-half of the stillbirths of premature weight was ascribed to placental and cord conditions and one sixth to the maternal conditions of toxemia, and diabetes. State-wide, fetal death certificates for 1958 ascribe 39 per cent of all fetal deaths to placental and cord conditions.

Premature birth takes a higher toll of infant life than any other condition and it is one of the ten leading causes of death among the general population in the United States as well as in Minnesota. While only about 6 per cent of Minnesota births are premature, the mortality rate among these babies is so high that deaths assigned to premature birth (unqualified) accounted for almost one-fourth (22.2 per cent) of all deaths during the first year of life in 1958 (Table IV). Many of the infants whose cause of death was reported as due to "premature birth" were doubtless too immature for survival. Others, mature enough to survive, may have died from some undiagnosed condition. In addition, birth injuries and congenital malformations are not infrequently the cause of death of premature infants but are

TABLE IV. LEADING CAUSES OF INFANT MORTALITY
(Minnesota, 1958)

Causes of Death	Number	Per Cent
Premature birth	434	22.2
Postnatal asphyxia and atelectasis	296	15.2
Other conditions of early life	189	9.7
Injury at birth	230	11.8

Communicable diseases	271	14.0
Other	199	10.1
All causes	1953	100.00

tabulated under these specific causes of death, rather than immaturity, unqualified.

The marked reduction in infant mortality during the past two decades is presented in Figure 3. There was a 40.5 per cent reduction in the total infant mortality from 1938 to 1958. For specific causes there was a 40 per cent decrease in deaths due to immaturity and atelectasis combined, a 31 per cent reduction in birth injuries, 27 per cent reduction in deaths due to congenital malformations, and a tremendous reduction of 62 per cent in deaths due to communicable diseases.

There were 1,953 infant deaths in 1958. Of these, 1,489 occurred during the first twenty-eight days of life. Thus, three-fourths (76 per cent) died within the so-called neonatal period. During the neonatal period, prematurity unqualified was responsible for more than one-fourth (28.6 per cent) of the deaths (Fig. 4). Postnatal asphyxia and atelectasis accounted for an additional 20 per cent. Congenital malformations and birth injuries each accounted for 15 per cent of the deaths. Erythroblastosis and communicable

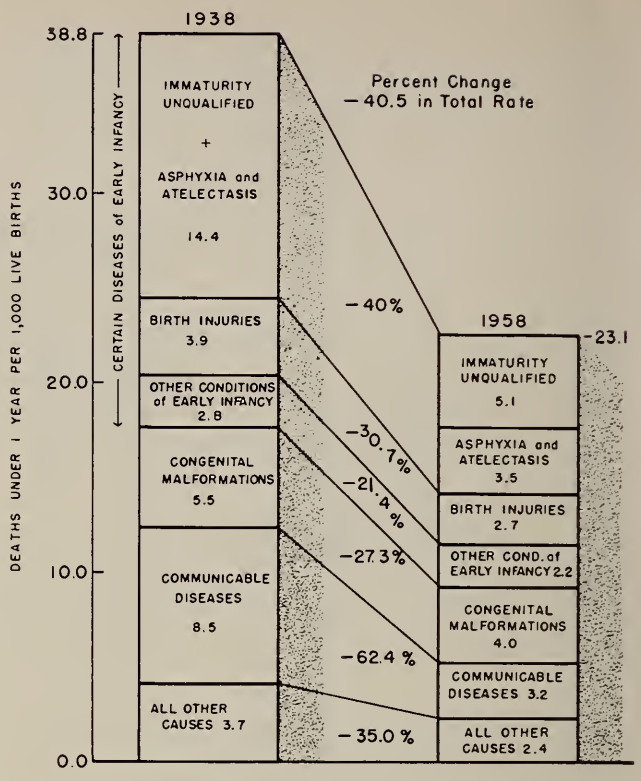

Fig. 3. Main causes of infant mortality by rates, Minnesota, 1938 and 1958.

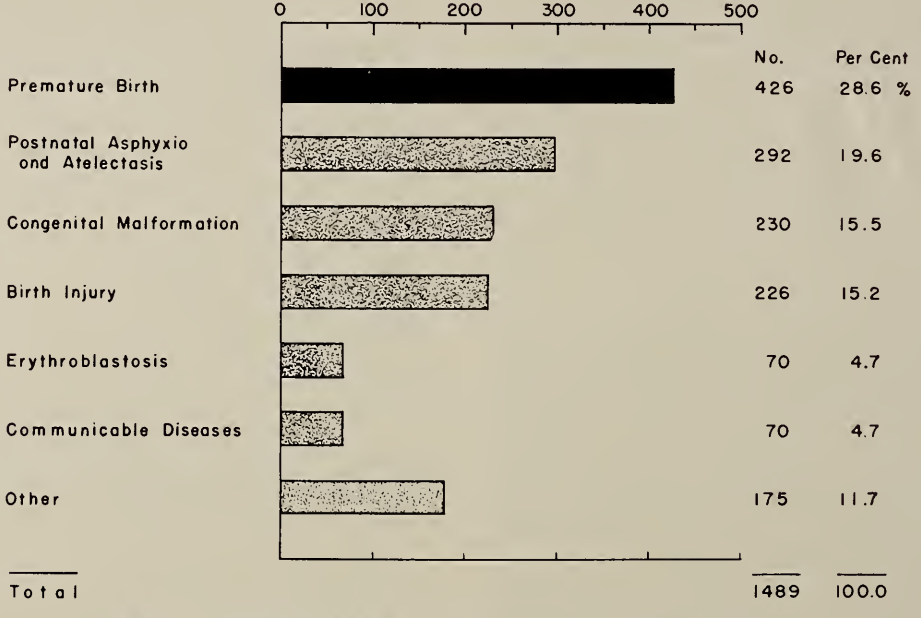

Fig. 4. Neonatal deaths by specific causes, Minnesota, 1958.

diseases each were responsible for slightly less than 5 per cent of the neonatal deaths. It is therefore important to consider this critical period of life.

In a large proportion of the deaths of premature infants, no cause other than prematurity can be determined. It is often difficult, if not impossible, to determine the cause of death of these infants, even in some cases where autopsy was performed. While the post-mortem diagnosis of the cause of death is more exact than a clinical diagnosis, it is dependent on the expertness of the pathologist and the correlation of the findings with the medical history and physical examination of the infant.

The five-year summary of the causes of death of 1,710 neonatal deaths in the Hennepin County study (Table V) shows that there were 1,239 premature infants, comprising 72.5 per cent of the neonatal deaths, with an autopsy rate of 59.6 per cent, and 471 full-term infants with autopsy rate of 86 per cent. The causes of death are the same in two groups; only the percentages are different. Abnormal pulmonary ventilation (Dr. Edith Potter's term)[7] which includes immaturity unqualified and means immature lung tissue, atelectasis, and hyaline-like membrane disease accounted for more than three-fourths of the premature infants, but for only 28 per cent of the full-term infants. Congenital anomalies were the leading cause of neonatal death in the full-term infants, one-third of the deaths (33.5 per cent), but accounted for only 8 per cent of the premature deaths. Blood dyscrasias caused 12 per cent of the full-term deaths and was the third leading cause of death, but caused less than 2 per cent of premature deaths. Birth trauma caused 7 per cent of the full-term deaths and less than 4 per cent of the premature deaths.

TABLE V. CAUSES OF 1,710 NEONATAL DEATHS
Hennepin County Perinatal Mortality Study, 1952-1956

Cause of Death	Premature (2500 gm. or less)		Full-Term (2501 gm. and over)		Total	Per Cent

TABLE VII. NEONATAL SURVIVAL AND MORTALITY BY BIRTH WEIGHT
(Minnesota, 1958)

		Survival Rate	Neonatal Mortality
Full term		99.34%	0.66%
Premature		81.1	18.9
2001-2500 gm.	95.6	4.4	
1501-2000	77.5	22.5	
1001-1500	45.1	54.9	
1000 and less	8.1	91.9	

Complications of delivery also play a part in premature neonatal deaths. The Hennepin County study of the types of delivery from 1952-1956 shows that in 60 per cent of the neonatal deaths among prematures, the infants presented cephalically; in 27 per cent they were breech deliveries, and 9 per cent were cesarean sections. Among full-term neonatal deaths 78 per cent were cephalic, 9 per cent were breech deliveries, and 9 per cent were sections (Table VI). Less than 5 per cent of all live births are breech deliveries and the cesarean section rate in Minnesota is between 5 and 6 per cent. The smaller the infant, the more likely it is to be delivered as a breech. In this study, breech deliveries occurred in 33 per cent of the prematures of 1,000 gm. or less; in 15 per cent of those between 2001 and 2500 gm. Breech delivery and cesarean section are particularly hazardous to the premature infant.

Now, let us consider the significance of actual birth weight in survival or death, as well as the time of death during the neonatal period. While

less than 1 per cent of full-term infants died during the first twenty-eight days of life (0.66 per cent to be exact), 19 per cent of all premature infants died during this same period (Table VII). The chances of a full-term infant surviving the neonatal period were thus twenty-eight times greater than that of the prematurely-born infant.

There is, however, a marked difference in survival rate depending on the birth weight of the premature. The prognosis is excellent in infants weighing 2001-2500 gms. (4 lb. 7 oz to 5 lb. 8 oz.), with only 4.4 per cent dying during the first month. The prognosis gets worse with decrease in weight. In infants between 1501-2000 gms. (3 lb. 5 oz. to 4 lb. 6 oz.) the mortality is 22.5 per cent; between 1001-1500 gms. (2 lb. 4 oz. to 3 lb. 4 oz.) 55 per cent died. Infants weighing 1000 gms. or less (2 lb. 3 oz. or less) had only an 8 per cent chance of survival, 91.9 per cent died.

The Hennepin County Perinatal Mortality Study has provided data on the age of death of prematures. The five-year summary in Table VIII gives the duration of life by birth weight. The first twenty-four hours were the most critical period of life, with two-thirds of the premature deaths in this period. One-sixth (15.6 per cent) occurred in the second twenty-four hours after birth, 12.6 per cent between two and seven days, and 5 per cent from one week to under one month. Eighty-two per cent of all prematures who died in the neonatal period actually died during the first forty-eight hours; only 62 per cent of the full-term infants died during this period.

In summary, infancy is a most serious period of life. Of those who die during the first year of life, three-fourths actually die during the first month of life, the so-called neonatal period. In the neonatal period, the chief cause of death is prematurity. Of all the premature infants who die during this critical period, two-thirds die during the first twenty-four hours and more than 80 per cent die within the first forty-eight hours after birth. We must, therefore, be particularly concerned with the prematurely-born infant and the first forty-eight hours of life.

The problem of reducing prematurity and its resulting high fetal and infant loss is quite complex. Early and adequate prenatal care with improvement of maternal dietary habits is essential. The importance of preconceptional care has, so far, received little attention. Better medical and obstetric management during pregnancy and skilled pediatric and nursing care during the early neonatal period, as well as adequate later care are of primary importance. Dr. Ethel Dunham,[6] who has written extensively on the subject, has summarized the situation as follows:

TABLE VIII. DURATION OF LIFE BY BIRTH WEIGHT
Hennepin County Perinatal Mortality Study, 1952-1956
(1710 Neonatal Deaths)

Duration of Life	Premature (2500 gm. or less)		Full-Term (2501 gm. or over)	
	Number	Per Cent	Number	Per Cent
Under 1 hour	175	14.1	62	13.1
1-24 hours	652	52.6	151	32.1
24-48 hours	193	15.6	81	17.2
2-7 days	156	12.6	103	21.9
8-28 days	63	5.1	74	15.7
Total	1239	100.0	471	100.0

> Saving these infants necessitates increasing efforts to prevent premature birth; getting more detailed information on deaths assigned to premature birth alone; spreading knowledge of and facilities for the special care to be needed by premature infants; and broadening through research the scope of knowledge in regard to the problems of prematurity.

Progress has been made during the past several decades as has been described; but there is still much more to be done. This requires the cooperative efforts of all concerned.

Metastatic Hypernephroma of Fifty Years' Duration

● *An interesting report of a patient living fifty years with a hypernephroma and metastases.*

C. W. WALTER, M.D.
D. R. GILLESPIE, M.D.
Saint Paul, Minnesota

From the Earl Clinic, Saint Paul, Minnesota.

THE FOLLOWING case report is presented to demonstrate the low grade nature of the malignancy in this case and the need for serial x-ray studies of the rate of tumor growth before giving a prognosis.

This patient, a woman aged seventy-four years, was first seen in March, 1950, for discomfort in the chest. At this time, she complained of fatigue, tightness in the chest, and a cough which had been present for six months.

Upon physical examination numerous rales were heard throughout both lungs. Laboratory examinations showed a hemoglobin of 11 gms. and a blood sedimentation rate of 110 mm/hr. (Westergren). The remainder of the examination was not significant.

A chest radiograph at that time showed multiple, variable-sized roundish lesions in both lung fields, which were thought to be metastatic lesions (Fig. 1). Origin

of the primary tumor was indeterminate at that time. X-rays of the gastrointestinal tract, lumbar spine and pelvis were negative except for the absence of the left kidney. The right kidney was of normal size. Re-examination of the pelvis and breasts were negative.

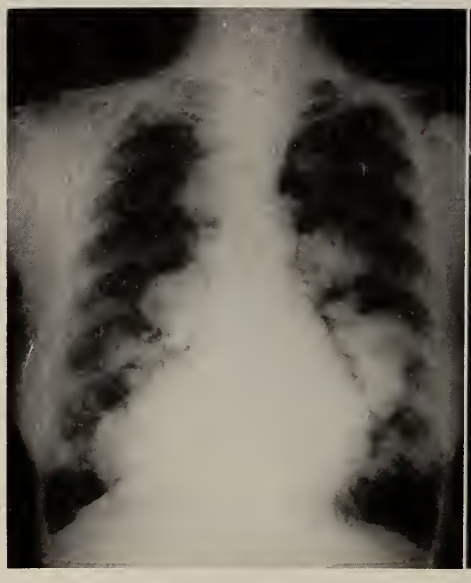

Fig. 3. Radiograph taken on May 19, 1953, showing increase in size and number of lesions.

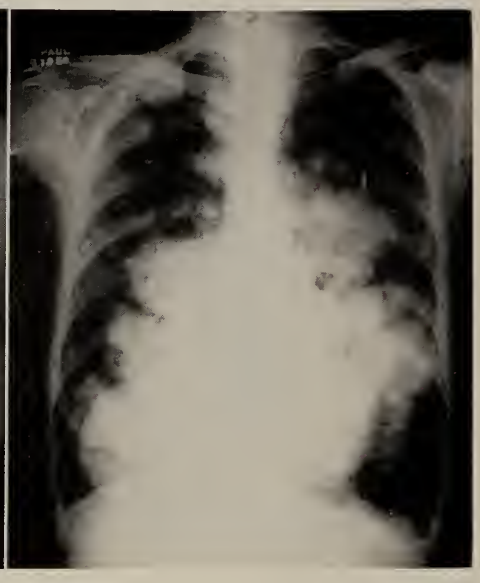

Fig. 4. Chest radiograph taken on September 19, 1956, showing marked increase in size and number of lesions.

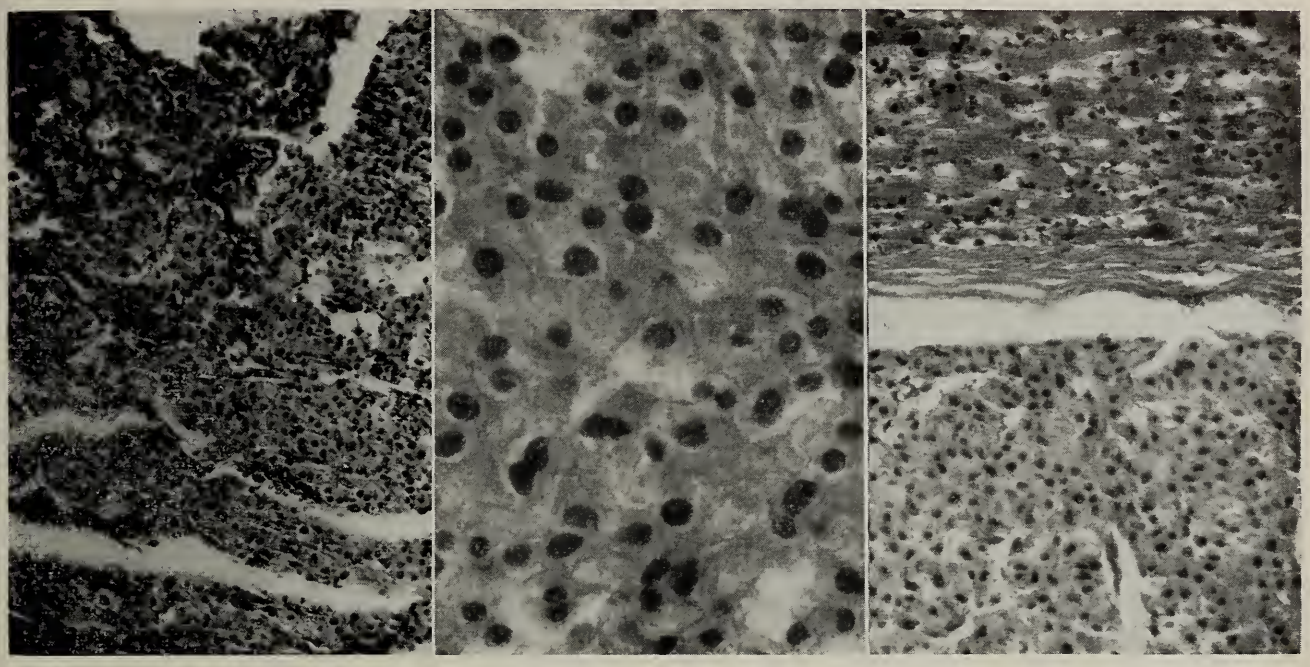
The past history of the patient was reviewed. She stated that about 1907, at the age of thirty-one, two years after the birth of her only son, she had noted a mass in her left abdomen and had consulted a doctor who advised its removal. The patient declined surgery at that time. Over the years, the mass gradually increased in size until in 1917, at the age of forty-one, its size caused her enough distress that she agreed to its removal. The surgery was performed at Ancker Hospital by John L. Rothrock, M.D., but no records or specimen are available. After surgery, he told the patient that it was a malignant tumor of the left kidney, necessitating the removal of the tumor and kidney. Following the surgery and until seen in 1950, she had had no medical care. She mentioned, however, that three years previous to this time, she did have chest radiographs at the Public Health Center during the period when radiographs were being taken to uncover cases of tuberculosis. The Public Health Center was consulted and radiographs taken on November 24, 1947, were obtained. This chest radiograph showed the presence of the same metastatic nodules but they were fewer in number and of smaller size than those evident on our recent chest x-ray (Fig. 2). In view of this slow growth, it seemed probable that the tumor of the kidney removed in 1917 represented the primary source of the metastatic lesions.

The patient was seen at frequent intervals from 1950 until March, 1957, at which time she was admitted to Ancker Hospital for terminal care. During this seven-year period, she had frequent attacks of pneumonia with severe dyspnea. She responded very well to antibiotic therapy for the first four years, but during the last three years her vital capacity became so poor that her exercise tolerance progressively decreased and she would become cyanotic on the least exertion. She was maintained on almost continuous antibiotic therapy during the last year. In 1954, a mass had been noted in the epigastrium and had gradually increased in size. She maintained her weight very well until the last two years when there was a progressive loss of strength and weight from 154 pounds in 1954, to 112 pounds in 1956. She also complained of increasing indigestion.

Radiographs of the chest were taken yearly in order to follow the progress of the metastatic tumors. Figures 3 and 4 represent radiographs taken in 1953 and 1956.



It was particularly of interest that although most of the nodules had increased in size, some of them had actually decreased in size during this period of observation.

On March 13, 1957, she was transferred from a nursing home to Ancker Hospital for terminal care. The patient was extremely dyspneic and was in an oxygen tent for intervals during her hospital stay. She gradually continued her slow terminal course and died on August 14, 1957. An autopsy was performed by John Noble, M.D., pathologist at Ancker Hospital, who has made available to us the reports and slides for this report.

Autopsy examination, performed on August 14, 1957, was non-contributory except for the following findings related to the metastatic malignancy: Upon physical inspection there was a left paramedian scar, measuring 13.0 cm. in length, extending from just above the umbilicus to the symphysis.

Thorax.—The right lung was bound down with apical adhesions. The right pleural cavity contained approximately 100 cc. of a serosanguineous fluid. The pleural

surface was studded with elevated, pinkish-grey nodules, the largest measuring about 3.0 cm. in diameter. The left lung was bound down by apical adhesions. The tissue, probably representing the renal pedicle. On cut section through this, no gross evidence of tumor was seen.

Figs. 5, 6, 7. Photomicrographs of metastatic tumor of the lung.

left pleural cavity contained approximately 100 cc. of serous fluid. The left pleural surface was studded with tumor nodules similar to those seen on the right lung.

Lungs.—The right lung weighed 1,401 grams. The surface of the right lung showed fibrous adhesions in the right apex. The surface was grossly nodular. On cut section, the lung was filled with tumor nodules which measured up to 9.0 cm. in diameter. The tumor was yellowish and white in color. Areas of tumor necrosis were seen. The left lung weighed 1,336 grams. It showed a picture entirely similar to that of the opposite organ. The nodules in the parenchyma of each lung were cauliflower in appearance on cut section.

Liver.—The liver weighed 2,338 grams. The surface of the liver showed elevated nodules and the edges were somewhat rounded. On cut section, there was an 18.0 cm. tumor mass in the right lobe of the liver. This tumor was cauliflower in appearance and it was yellowish-white and necrotic in the center. The remainder of the liver parenchyma was not remarkable.

Kidneys.—The right kidney weighed 217 grams. Its capsule was opaque and quite thickened. The capsule stripped with ease, leaving a smooth surface on cut section; the cortex and medulla appeared larger than normal. The pelvis and ureter were normal. The left kidney was represented by a nub of fat and connective

Microscopic examination of the lungs showed large areas which were replaced by a metastatic growth in large lobulated areas. In some places, the tumor was necrotic. Where it was well preserved, it was composed of sheets and cords of rather large cells with abundant light staining cytoplasm. There was considerable variation of nuclear size and shape. A few abnormal mitotic figures were seen (Figs. 5 and 6).

Sections through the liver showed that the liver was replaced and compressed by tumor similar to the metastatic hypernephroma seen in the lung (Fig. 7).

Final Diagnosis.—Hypernephroma of the left kidney, resected, with metastases to lungs and liver.

Summary

This is a case of hypernephroma of the left kidney, first noted in 1907, when the patient was thirty-one years of age. She was operated on ten years later, at the age of forty-one years, because of the size of the tumor. There were no symptoms of hematuria or urinary tract infection, either before or following surgery. In 1947, the first evidence of metastatic lesions in the chest was found. Serial radiographs taken during the last ten years are presented. The patient died at the age of eighty-one years, or fifty years after first noting a tumor in her left abdomen.

Journalism in

ARTHUR H. WELLS, M.D.

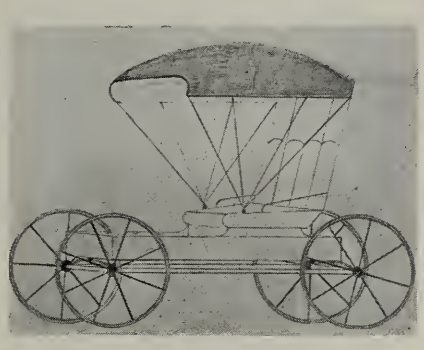
Editor-in-Chief of MINNESOTA MEDICINE and Pathologist at St. Luke's Hospital, Duluth, Minnesota.

Presented at the Annual Meeting of American Medical Writers' Association, October 2, 1959, St. Louis, Missouri.

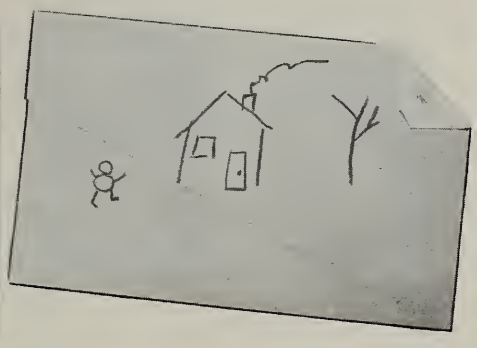
Yesterday's MINNESOTA MEDICINE and the buggy have much in common. Today the journal is a crumpled, crayon-smeared sheet in the hands of children. Tomorrow's publication will come when good judgment and a pioneering spirit demand and the Jehovah complex permits.

OUR president, dean of American medical editors, leader and servant, Morris Fishbein, has requested a twenty-minute review of the recent changes in MINNESOTA MEDICINE and the experiences which brought them about. These changes and experiences will be covered as they relate to typography, procurement, editing and financing in our state medical journal and will be followed by a brief listing of suggestions for the future promotion and control of all forms of medical communications within the state.

Current Trends



Medical editors have watched with enthusiasm the renaissance which has been taking place among the medical journals of our country during the past five years, a trend initiated in large part by the educational programs promoted by the American Medical Writer's Association and by the State Journal Advertising Bureau. This application of advancing knowledge in the science of semantics has seen vigorous usage in the more highly competive and sophisticated national lay magazines for many years. Within the decade, a warning bell was sounded when a national magazine with a century of experience and with a large circulation failed because of its inability to see and to recognize the importance of the trend. It maintained a rigid policy of strict conservatism in visual style. May we conclude that in journalism, as well as in medicine, that which has been highly successful in the past need not be acceptable in the future?



In the last few years we have seen new national medical journals *(Postgraduate Medicine* and *GP)* launched and soaring to leadership in the field. They have made bold and successful efforts to crack the sound-barrier of satisfaction with the *status quo*. They have utilized all the advantages of psychology in modern journalism to attract and hold the minds of men. If busy physicians are reading these glamorous, yet scientifically informative publications, will the older, well-established and more reserved periodicals receive the same attention they did in the past?

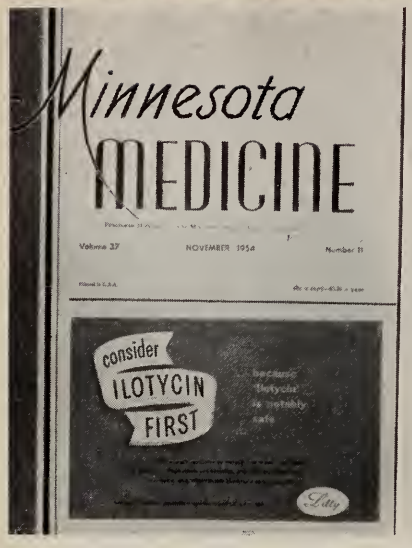
Typography

Ten physicians representing the newly-formed and personally-selected Board of Editors of MINNESOTA MEDICINE, armed with a loose-leaf binder to record their experiences and a style manual on medical writing, began six years ago to grope their way through the maze of knowledge known as journalism. Ambushed, beseiged and hobbled by a traditionally long-standing Editing and Publishing Committee; by a Council which has always considered MINNESOTA MEDICINE faultless and the leader of state medical journals, and by the journalistic inexperience of all the physicians involved, it is a wonder that this board of voluntary amateurs ever survived.

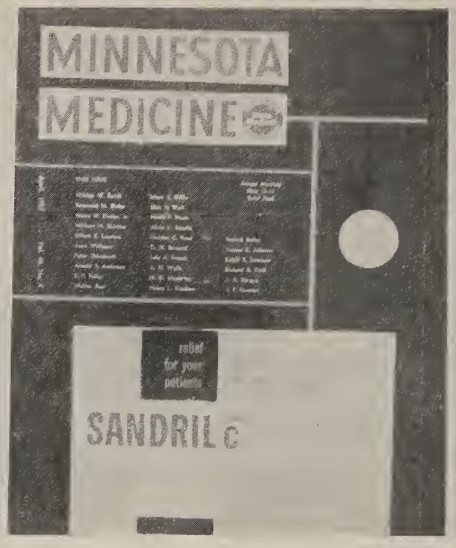
From the outset it was apparent that the most intriguing, and possibly the most rewarding field of activity for the committee concerned typography or the visual aspects of printing and their psychologic effects. We learned that this general subject of style might be divided into at least eight different areas for consideration: format, cover, table of contents, headings, body type and column treatment, illustrations, lay-outs, paper, ink, press-work and engravings. We also learned, following a critical survey of the journals of the S.J.A.B. by

O. M. Forkert and Associates of Chicago, that we rated poor in style in most areas of usage and below the average of other state medical journals. Five years later the same group of consultants for journalists and advertisers found MINNESOTA MEDICINE ranking in typography among the three best of the state medical journals. The scientific content of these journals was not a consideration. The difficulties experienced by the Board of Editors in bringing about this moderate change, using standards generally accepted by journalists is a part of this presentation. The efforts of the Board during its first year were characterized by repeated frustrations concering suggested alterations in the printing of our Journal. We finally realized that our printing company, long-established, deservedly successful, with multiple facets of interest and a heavy burden of varied responsibilities, had lost perspective. After several varied approaches to the problem, it became obvious that this would be a chronic ailment and best cared for, in this instance, by simply pushing the patient around and I don't mean in a wheel chair.

Cover



A recent cover of our publication (Fig. 1) should have been given a journalistic citation of some kind since it displayed at least fifteen styles of type with each issue. It proudly indicated its national origin. In some issues, postal inspectors could see at a glance that it was within the law. The price per single issue was clearly displayed perhaps to prevent cheating at news stands. The principal and inexcusable feature was that the cover undersold the publication to its prospective readers and advertisers by displaying a dominating advertisement.



The Board of Editors was eventually permitted to partially change this monstrosity if there were no additional cost. The first new cover (Fig. 2) contained the essentials for identification, a listing of authors, and a guide to the contents page. To eliminate the advertisement of a pharmaceutical house from the cover, it was finally necessary to convince Mr. O. M. Forkert that it was his duty to talk at a combined meeting of the Council, the Editing and Publishing Committee, and the Board of Editors in Minneapolis. The cover which resulted from this meeting (Fig. 3) has the essentials for identification plus what we hope is a dignified "sales pitch" for the contents. Some may see a "pitch" for future manuscripts in the unconventional listing of authors in an "honor plaque." To me, these authors of scientific content are the making of the journal, and they should be given at least this recognition.

A needed future improvement in the cover of our Journal is an ever-changing, skillfully-staged, appropriate art work in multiple colors, related to occasion or content, having a motivating intensity approaching persuasion (see *The Journal of the Michigan State Medical Society).*

Contents Page

According to our Readers' Interest Survey (described later) the Contents Page was the most important single part of our journal. To this end, we changed from one page (Fig. 4) to a coverage by two facing pages (Fig. 5). This was also permitted by the Council provided that there was no

additional cost or loss of advertisements. After gentle, persuasive, forceful and belligerent contacts, this was accomplished first by combining contents with other essentials on two opposing pages. Later, an advertiser's demand for space opposite a listing of the officers of the society permitted a separate posting of instructions to authors, subscribers, postmaster, et cetera. Thus a third change in the table of contents (Fig. 6) provided for a sub-division and listing of editorial matter in some detail, not yet complete but improved. The prominent space devoted to "The Advertising Pays for Your Journal" and the old gimmick of listing the Minnesota medical societies affiliated with the journal is for the benefit of both advertisers and physicians. We are not opposed to money or apparent scientific stature, and we do like to have our friends grouped about us when in the public eye.

Headings

Four stages of improving headings are apparent in today's medical periodicals. We are in the third phase. Figure 7 shows the rigidly-centered and overly-balanced simplicity of an unimaginative period. From the title in Figure 7 you will know that there is an interesting photo hidden in the presentation. This could have been used to dress up the entrance-way for a prospective reader. Figure 8 represents a minimum of flexibility concerning headings and would seem to be simple enough if you were not trying to bring about the switch from Figure 7 to Figure 8 in a journal. After all, how many centuries passed while man progressed from scratching pictures of animals in stone to executing abstract art in oil? Figures 9 to 15 represent what our abilities and budget permit at the present time.

It will be noted that in most instances no additional space is required for a given manuscript. A continuity of styles in print is, at present, a feature of our headings and contrasts with the variation in staging of the elements utilized to avoid any duplication of general appearance in a given issue. This can be accomplished technically by the help of a chart illustrating many of the possible variations for a given-sized space. Dynamic cropping and dramatic positioning of illustrations, boxes and defining features is an art and should be done by artists. However, we are functioning on a shoestring so that after the page proof leaves my desk I am never sure whether the final printing will bring pleasure or discouragement, thrills or anger. No "run arounds" (except for references) are permitted to disturb our readers at the ends of manuscripts. Thus the size of the heading is determined, in part, by the fraction of a page length remaining blank when the galley proof is pasted up from the end forward. The individual on the Board of Editors who reviews a manuscript writes the prefatory abstract or "blurb." The use of color and appropriate art drawings in our headings and body must await the future.

We have temporarily agreed to a second-choice style of body print. A font of a more masculine and more easily read style of type would cost our printer twenty-five hundred dollars ($2,500.00). Our margination, gutters and column width are now said to be good. A perfectly white paper stock similar to that used in *GP* and *Surgery, Gynecology and Obstetrics* is a must for the future.

To my amazement, a few months ago at the

time the Federal Government insisted upon a continuous numbering of pages of advertising with pages of scientific and business matters, there suddenly appeared in our journal, an entirely new numbering system, and a wild distribution of valuable editorial information among advertisements in the rear of the publication. This unauthorized mutilation of the 1959 volume of our journal can never be corrected. No one can predict from which direction the next storm will blow.

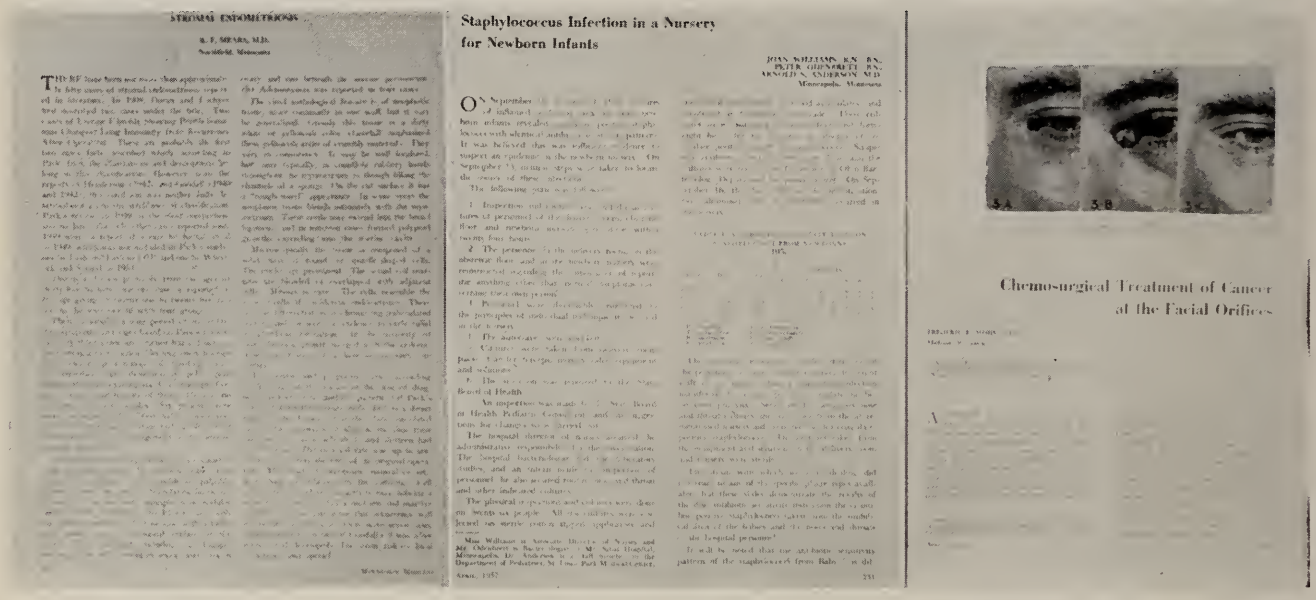
The need for many alterations in the present uninspiring headings of feature sections of the journal must await the birth of inspiration and knowledge in the editor and the Board or the employment of specialized talent. A start may be the insignia (Fig. 16). This is a frank copy of others and excusable only on the theory that to become an expert one must first imitate the experts.

Procurement

Much of the early efforts of the Board of Editors was expended in locating sufficient numbers of manuscripts to keep the monthly periodical in print. A principal obstacle to obtaining manuscripts was long-established frictions between large segments of the physicians of the state. It must suffice to say that at one time two medical organizations vied to represent physicians in the state. In a separate conflict, two journals represented two opposing groups. Removing the editorship to neutral territory (Duluth) six years ago plucked a thorn so that a wound might heal. We remain in a desperate struggle with the locally lay-owned but medically-supported magazine *(The Journal Lancet)* with its well-trained, full-time, specialized personnel, access to printing presses for special services, prestige through published names for medical sponsorship, financial backing for possible research grants and the will to survive. The limited circulation of most state journals, as compared to a few national publications, is a continuous handicap to the former. Editorials written on the problems of the society's publication, solicitation of intra-state medical societies for their support, conduction of a Readers' Interest Survey, and finally, a simple highly successful method of personal solicitation of those individuals presenting medical subjects thought to be suitable for our journal at the many medical meetings in the state, resulted in a good flow of excellent material. The publication of two supplementary issues (Fig. 17 and Fig. 18) became a pleasing and necessary service to our readers. The extra manuscripts permitted more discrimination in the selection of those published. More space was needed. Severe limitation of the publication of a "History of Medicine in Minnesota" and a partial reversal of a policy of printing new book reviews (free advertising for publishers) helped provide space for items of greater value to our readers (their choice).

The Readers' Interest Survey (Fig. 19) conducted at an annual meeting by the Research Division of the School of Journalism of the University of Minnesota enlightened us on many things. These included the fact that our monthly MINNESOTA MEDICINE was read by the physicians of our state more than the weekly *Journal of the American Medical Association*. No other single journal came near these two in usage. However, the third in line was a pocket-sized "throw away," a lay commercial periodical specializing in summarizations of legitimate medical publications. Within the decade, many of these parasites of medical journals have cunningly played upon a strong universal trait of man. It has not only become an accepted custom but an honor to up-grade the covers and pages of their magazine with personal pictures and names of medical celebrities.

The order of preference of parts of the journal revealed by the survey was: table of contents, regu-



lar scientific articles, editorials, physician's diary. . . . There was a strong demand for brief concise summaries on applied medicine. We have attempted to fulfill this educational need, now partly supplied by the "commercials," through promoting a section on Current Concepts. Much better organization of the voluntary assistance in this field of procurement is needed in the future.

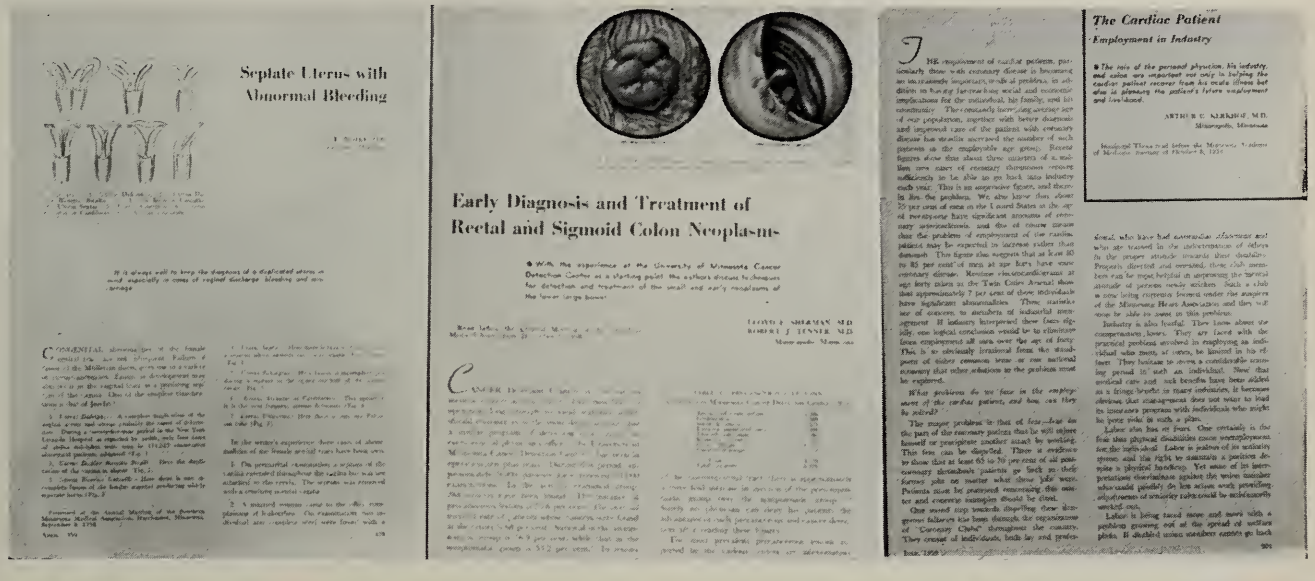
An annual audit of the journal for the frequency of subject matter of scientific manuscripts in the various specialties of medicine permits a concentration of procurement efforts in the poorly-represented disciplines of medicine. Thus, a continued series of manuscripts appeared on accidents of childhood initiated by the pediatrician on the Board of Editors. A long-felt need for a section on Public Relations was realized when such a person joined the Executive Staff of the State Medical Association office. Business functions are now partly covered by summaries written by chairmen of the various committees of the Association in a section designated as Committee Action.

The true value and importance of organized medicine, including its principal media of communication, is learned early in Minnesota since the Association now gives the journal to the members of the junior and senior classes in medicine at the University of Minnesota.

In spite of the temporary success in the procurement of a quantity of printable matter, the Board of Editors has much to learn and do. Our greatest usefulness to the busy generalist would be the production of a dependable authoritative source of concise informative reviews of recent concepts in applied medicine. We are pitifully lacking in manuscripts covering clinical research in applied medicine including: signs, symptoms, laboratory procedures and therapy as they have been observed in diseases in significantly large groups of patients. Here is the ideal area where the group as a whole could subsidize the individual thus promoting both research and education in its most popular form.

A news section in addition to our popular Physicians' Diary would please many readers and close a gap of time. The section on Medical Progress (a complete coverage of a limited subject) requires much more planning in advance.

Editorials on the numerous controversial political, business and scientific aspects of medicine could, in themselves, carry a medical journal to fame and be of unestimable service to medicine.



Editing

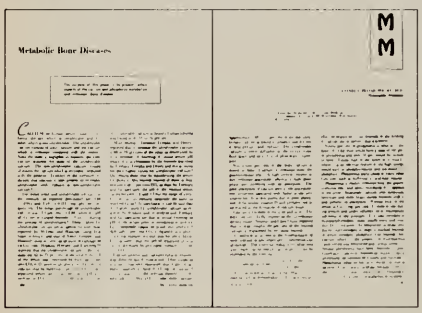
The Board of Editors has been fortunate in having among its members a physician who is a specialist in editing from the Section on Publications of the Mayo Clinic. A routine review of editorial errors in past issues has been a continuous and frequently depressing feature of the bimonthly meetings of the Board. Multiple editings of manuscripts by the individuals on the Board of Editors and the lay writers hired by the publishing company, simply divided the responsibility for errors. It was not until specific responsibilities were agreed upon that a decided improvement occurred. The responsibilities were assigned to best utilize the specialized training of the voluntary

physicians of the Board and the professional lay editors of the publisher. We still have no means of checking references or the volume index.

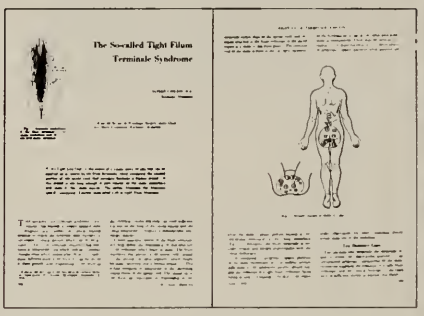
The ever-popular Case Report remains "the short change in medical education which is its capital." Our acceptance of manuscripts is prejudiced in favor of publishing the case reports of isolated physicians. Special funds are available for rewriting, transcribing and producing illustrations for this group of doctors located in large cities as often as in small communities. One of the basic purposes of our journal is to permit and encourage self expression of the membership.

concentrated effort on the scientific aspects of medicine given freely by the authors. The adherence to the unwritten laws of this ancient heritage have resulted in an "accelerating acceleration" of new discoveries ever more practical and helpful to man. The advancements of each decade outdo the previous by a large margin. Medical educators are in a continuous state of flux trying to crowd ever more and the most important of this information in the same four years of training. Physicians in general practice or the specialties are frequently bewildered by the continuous stream of practical knowledge. The ways and means of

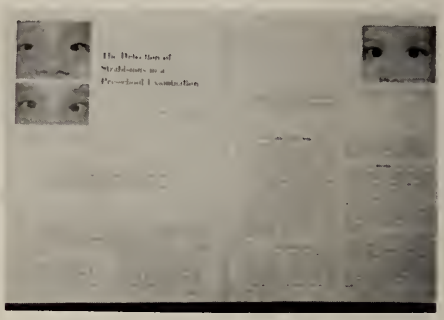
We do not aspire to the publication of perfect English. We try to publish the unmistakable meaning of the author and to help him clarify and simplify sentence structure. The spelling and punctuation should be reasonably good. To assure a uniformity of bibliographic references and illustrations, we publish instructions to authors in each issue. Greater attention must be paid to requiring a summary which summarizes. The data in tables and text should coincide. Brevity must be enforced. At present, this can not be done to the pleasing degree which characterizes the *American Journal of the Medical Sciences.* To create a a literary style is beyond our ken and purpose.



Financing



Few customs of man are quite so idealistic and beneficial as the free exchange of knowledge concerning medical diagnosis and care. Each issue of our journal represents hundreds of hours of



making it possible to efficiently communicate this vital information to the practicing physician is becoming an ever-increasing problem. In especially urgent situations, such as staphylococcus sepsis in hospitals, the Federal Government and private agencies have subsidized research and the collection and distribution of clinical and laboratory findings of many sources. Most medical journals must depend upon advertising to help carry the heavy burden of publication costs.

It is essential that the financing of medical journals be handled in such a way as to protect the dedicated purpose of the publication. In Minnesota, no one physician or group knows the basic details of the financial aspects of the official journal. Here we remain babes in the woods. A committee appointed for the purpose follows fifteen years of benevolent and trusting tradition of no interest, no knowledge, no ability, and no action, yet emotionally brittle—in other words, "all thalamus and no cortex." This is a common descrip-

tion of committee action in many fields of interest and does not necessarily reflect on individuals in the committees. Our printer runs the show, collects the money and makes the reports. The percentages of give and take on this and that are all his worries, not ours. Economic matters pertaining to: exchange journals, distribution of extra journals in foreign countries, promotion of circulation, differential rates for professional and commercial advertisements, subscription price, the economics concerned in methods of printing, grades of paper, uses of color, mailing procedures, delayed publication of practically every issue, knowledge of various types of agreements with printers,

the criteria for selecting good printing companies, cost factors using color for line drawings in headings, the color "borrowed" from adjacent advertising, maintenance of comparative annual committee records, criteria, need and promotion of advertising adjacent to editorial matters, a critical check of each issue for weaknesses and areas of conflict between science and advertising, et cetera, would be fundamental to any organized business, but apparently not to "organized" medicine. Austin Smith once saved the American Medical Association over $100,000.00 a year by a simple change to a grade of paper not detectably different from that which had been in use.

There is no business or profession so keenly alert to the value of specialized talent necessary and the new products of research in its own field as is medicine. The new and eminently efficient techniques in communications including video-tape and pay television, not to mention the "memory" of an IBM robot, are now putting the finger on the State Medical Association. These advancements in means of communication must be put to work as soon as possible to handle those types of medical education best suited to their nature. New sources of money must be found. The same idealistic humanitarian policies of management and control must be maintained.

Future Organization

Like any other business, the basic departments responsible for the success of a medical journal must work together. In a journalistic enterprise, the editor-in-chief is the natural person to be responsible for co-ordinated action. The survival of an individual or a department, the product of defective political practices or poor judgment would be the editor's responsibility and not his enforced burden. To stimulate originality and progress, each department should have a chairman selected by the editor. These chairmen should constitute an executive committee with special periodic educational requirements. A paid journalist should be the executive editor and a guiding light to the voluntary medically-trained editor and members of the Board of Editors. A partially self-explanatory diagram is shown in Figure 20.

Conclusions

In the past, physicians have underestimated the value of modern typographic methods in documentation of their scientific advancements. It is apparent that they are not only pleased with the new manner of displaying their works, but will eventually demand it. The increased usefulness through a scientifically-correct method, and the reduced costs through increased circulation and advertising will eventually threaten the very existence of the less progressive medical journals wishing momentarily to attract and hold the minds of men. Beyond this, newer and more efficient techniques of communication combining oral and visual stimulation (such as in video-tape) may eventually, at least in part, replace the customary written word.

Six years of personal experiences with the roadblocks of long-established customs as editor-in-chief of a state medical journal briefly outlined in

the text leads to the following plea for a hearing.

Doctor, consider these twelve observations for their worth. They are directed at you and your State Medical Association.

1. The best in all fields of applied medicine is a nearly fantastically changing body of knowledge.

2. You strive desperately to ride the crest of this rapidly-moving wave of scientific progress.

3. This knowledge and the ability to use it is your stock-in-trade as well as a principal means to satisfy any need you may have to do something for others.

4. You welcome any relief in this life-time struggle to keep abreast and supply the best.

5. The nearly universal recognition of the importance of postgraduate education is reflected in the fact that it is considered the first function of nearly all medical organizations.

6. The two principal methods of participation of the Minnesota State Medical Association in this field are its journal and the annual meeting. Both have been receiving a minimum of support.

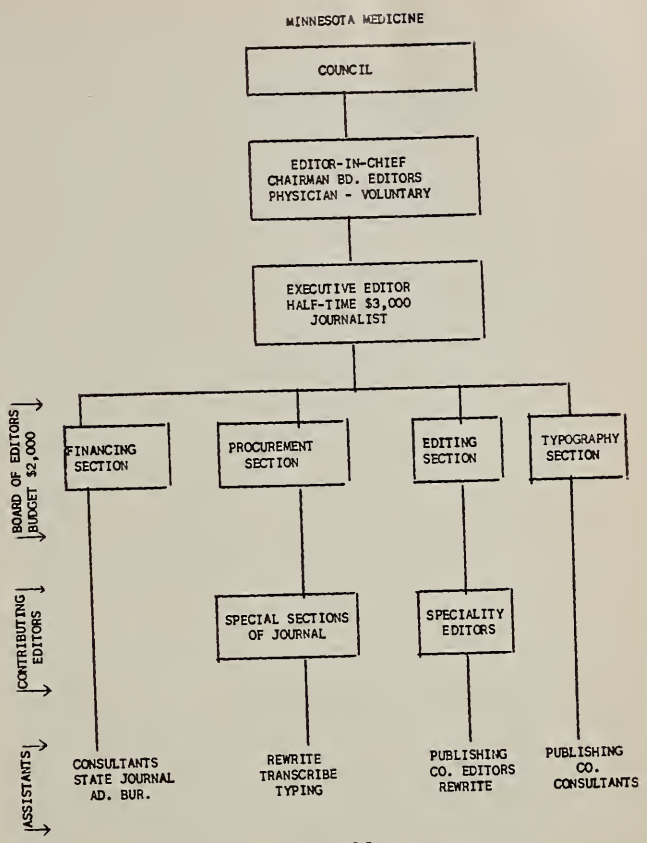
7. The resulting void has caused an accelerating trend for other societies, institutions and commercial organizations to take over this service basic to the practice of medicine.

8. Assimilation, digestion and retention of knowledge is a primary function of a science concerned with efficient and accurate communication.

9. Thanks mainly to the research and ingenuity of non-medical men, we are now at the threshold of a new era in communication.

10. Organized medicine at the state level must grasp this life preserver which has suddenly and miraculously appeared on the presently all-consuming waters of business in medicine.

11. The proper control and promotion of some



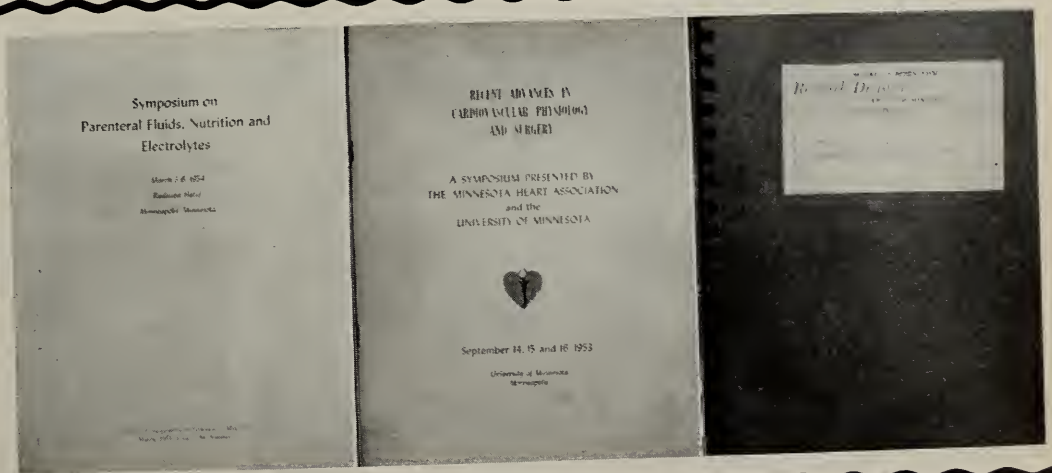


Fig. 20

of the new forms of communication of medical science is now within the reach of the State Association and through it eventually the coordinated action of the AMA and other states to utilize the talent of the nation.

12. Success in the organization and control of the usage of the recently-established pay television, video tape, modern journalism and other developments in the science of semantics will depend upon a radically new and informed approach to what today more than ever before is the first function of the State Medical Association.

HOMICIDE

A Legal and Social Study of Victims and Assailants

A Law-Medicine Center reflects inter-disciplinary thought not only in instruction but also research. The Center in Cleveland utilized this fact for its first major research project—a study of homicide in the urban, industrial community of Greater Cleveland. Major contributions to this project were made by the Coroners Office (forensic pathology and forensic toxicology) and the sociology, social work as well as law faculties of the University. Identification of the real cause and manner of death, not the apparent, can only be achieved in a scientific laboratory like the Cuyahoga Coroner's Office. Given this information, a study of the County Prosecutor's records for the seven years' covering the homicide study revealed the manner in which the legal process handled the 662 cases which emerged. Once identifying these 662 cases, a sociological study of the victims, assailants and neighborhood crime scenes involved in the individual homocides was undertaken. The mass of data collected produced interesting facts: 450 of the 662 incidents were felonious homicides, 157 were justifiable, 51 could not be classified; the police apprehended 95.5 per cent of all assailants; 26.3 per cent were convicted as charged, 45.5 per cent were convicted of lesser offenses, 28.2 per cent were found not guilty; 76 per cent of the felonious homicides were committed by Negroes who represented 10.7 per cent of the Greater Cleveland population; no significant differences with respect to the disposition of the criminal cases of white and Negro defendants appeared; women accounted for only 13.9 per cent of the felonious homicides; male defendants had a 10 per cent higher conviction rate than females; only 13 per cent of males eligible for probation were granted such but 40 per cent of the females were so favored; 50 per cent of the victims had alcohol in their body; 55 per cent of the homicides were caused by firearms, cutting and piercing instruments were used in 25 per cent of the cases and blunt instruments in 7 per cent. In the overwhelming number of cases the homicides were produced by (1) quarrels of a mostly petty nature, (2) marital discords in which one spouse kills the other, and (3) love or sex disputes in which the deceased was slain by one other than the spouse or "common law" mate. Such legal research is valuable for several reasons. The administration of criminal justice, particularly for homicide, can be evaluated. Corrections in legal procedures or enforcement techniques are possible. In a nation like ours, without a Ministry of Justice as in some European states, improvement in criminal justice administration is sporadic, disorganized and often irresponsible to say the least. Inquiring minds in a University environment can make major contributions to progress in criminal justice through inter-disciplinary research.

The same holds true for the social aspects of homicide—to remove the causes of the crime and prevent their occurrences. From the legal research, Negroes would appear to be the major cause of homicides in the urban community. The social study eloquently refutes this gross observation. The homicide rate in Negro areas differs greatly. In one area it is three times the rate found in another area. What other differences are revealed between these two areas of Negroes? The area with the lower homicide rate has nearly $700 more in median family income, three years more of education completed, 11 per cent less density of persons per net acre of living space, 30 per cent less substandard housing, three times as many owner occupied dwellings, over 20 per cent less infant mortality and tuberculosis cases, 55 per cent less illegitimate births, 70 per cent less overcrowded housing.

It is not the color of skin but the economic, social and cultural environment which are controlling factors in homicide areas. To interpret this fact with supporting data could go a long way to resolve a major domestic issue confronting America—the relationship of Negro and white citizens expecially in our Northern urban, industrial areas. With knowledge of the changes in employment practices to result from further revolution in industry—automation, the impelling need today is to comprehend the problem of more

leisure time, more unemployable persons because of lack of intellectual capacity. From the homicide study, leisure time for unskilled workers contributes to the homicide incidents. Basic thought in such areas as mental development, educational practices and governmental policies is vital if the whole crime problem as reflected by the homicide study is not to conquer us through the replacement of the free society by the slave society.

This primary homicide study soon to be published in book form actually asks more questions than it answers. Virgin territory was tilled, the first crop is not always the finest quality. Continued investigative labor in a University environment with co-operation of concerned public offices and private agencies will provide more and better data and opinions. The ancient problem of man's slaying man may well succumb to modern intellectual attack when the inter-disciplinary army advances. The Law-Medicine Center is one component of that army.

Western Reserve University

INTERMITTENT POSITIVE PRESSURE BREATHING (IPPB/I)

Intermittent Positive Pressure Breathing Therapy is a matter of progressively increasing interest and controversy. Manufacturers of various commercial devices in this field report a steady increase in demand for such apparatus, and in November, 1959, they met with The American Association of Inhalation Therapists in Philadelphia to discuss inhalation therapy, much of it related to intermittent positive pressure breathing.

Pressure breathing dates back to mouth-to-mouth resuscitation in Biblical times at least. Since then various forms of pressure breathing have been used and accepted in artificial respiration, infant resuscitation, pressure face masks, compression of the bag by anesthesiologists, the Drinker Respirator, and numerous other breathing and resuscitator devices. It is apparent, however, that the pressure application is not the same in all of these accepted uses, and therein lies the first source of misunderstanding in pressure breathing. In any discussion of this subject it is imperative that the exact type and application of pressure be defined before understanding and evaluation can be made.

Much of the present clinical interest centers around Intermittent Positive Pressure Breathing in which there is a gas flow under positive pressure during the inspiratory phase only, (i. e. IPPB/I), expiration being entirely passive. Commercial devices to accomplish this are numerous and they generally incorporate an aerosol nebulizer in the pressure circuit. Bronchodilator, detergent, and/or antibiotic agents are the usual therapeutic aerosols. Application is by face mask or mouthpiece.

The clinical situations in which the use of IPPB/I has been effective include:

1. *Chronic Pulmonary Disease.*—Emphysema, silicosis, bronchiectasis, bronchitis, asthma, and other infectious or bronchospastic alterations of the lungs are frequently much improved by this combined pressure and aerosol treatment.

2. *Hypoventilation.*—Post-surgical patients, particularly those with abdominal incisions, present markedly reduced vital capacities which encourage the complications of atelectasis and pneumonitis. Pressure breathing is effective in preventing such complications. The hypoventilation of neurological disorders, such as poliomyelitis and Guillain-Barré syndrome, can be greatly relieved by this mechanical assistance. For reduced ventilation in coma, and barbiturate intoxication, or in instances of complete apnea, the use of pressure breathing can be life-saving.

3. *Intoxication.*—Excessive gas accumulations, particularly carbon dioxide in the carbon dioxide narcosis syndrome, and even alcoholic excesses can be relieved by hyperventilation with intermittent positive pressure breathing of this type.

4. *Pulmonary Edema.*—Improved ventilation with the addition of the small pressure gradients of IPPB/I have been found to be therapeutically effective, in various types of pulmonary edema.

5. *Crush Injuries of the Chest.*—The use of pressure breathing, with or without tracheostomy, has provided comfortable ventilation for these patients whose ability to accomplish this on their own has been seriously compromised.

6. *Intractable, Non-productive Cough.*—The use of IPPB/I on the patient with a persistent bronchial irritation following an upper respiratory infection has been empirical but frequently helpful.

7. *Diagnostic Test.*—The effectiveness of ventilation with IPPB/I has been used in the determination of maximum blood oxygen saturation for the diagnosis of vascular shunts.

Many of these applications of IPPB/I depend for their effectiveness on the combination of increased ventilation and dispersal of aerosol medications. Whether their dispersal with pressure is more effective than the simple voluntary ventilation methods of accomplishing the same purpose is a point of debate and varies with individual patients. Other uses of IPPB/I depend for their effectiveness on the production of maximum ventilation per se, as in poliomyelitis and barbiturate intoxication, post-surgical pulmonary complications, and pulmonary edema. Whether the machine accomplishes all of this alone or is primarily a fulcrum for increased personnel attention to ventilation and the bronchial toilet, is another point of debate.

There is no doubt that many good results can be accomplished without pressure breathing apparatus, as the British do, by the application of proper physiotherapy techniques. However, the present shortage of trained personnel and nurses in our American hospitals has made the use of this mechanical device a practical vehicle for the management and prevention of these pulmonary problems. The physiotherapists, furthermore, have welcomed the addition of pressure breathing apparatus as an effective adjunct to their program.

IPPB/I has been used in The Buffalo General Hospital for over 6 years, with a total of 28,000 patient days of treatment with 32 machines. The incidence of post-operative atelectasis by record room statistics has been diminished, while the improvement in the cases of chronic pulmonary emphysema has been equally, but not universally, demonstrated. At present a study is under way to evaluate its effectiveness in the distribution of combined antibiotics and enzymes for improvement in the intractable pulmonary infections and results to date have been encouraging. So far, there have been only three known instances in this hospital of pneumothorax coincident with the use of IPPB/I. No other complications have been noted with any significant frequency.

On the basis of this experience it is felt that IPPB/I is a safe, effective method of accomplishing good clinical results in the situations outlined above. It is useful, however, only if (1) it is used for the proper indications, and (2) it is applied with the proper technique.

CLEFT LIP AND CLEFT PALATE

There is a bright future ahead for the 4,000 babies who will be born in the United States with cleft lip and cleft palate during 1960.

This hopeful outlook is revealed by Eugene T. McDonald, Ed.D., prominent speech and hearing specialist and director of the Speech and Hearing Clinic at the Pennsylvania State University, in "Bright Promise"—just published by the National Society for Crippled Children and Adults.

The advances in surgery have made it possible to repair lips and make adequate functions possible in many palates. Dental techniques have been developed for reconstructing by prosthetic means those palates which cannot be repaired surgically. Speech therapists today know how to help children with cleft palates develop good speech. Furthermore, there are helpful sources for information on problems of cleft palate, as well as resources for treatment, including state and local Easter Seal societies, state crippled children's services, many public schools in metropolitan areas and the speech clinics at colleges and universities.

Well illustrated with diagrams and "before and after" illustrations, "Bright Promise" traces causes of cleft lip and cleft palate, describes four major types and follows through on some of the technical advances in corrective procedures.

In pointing to studies of personalities of children with clefts, Dr. McDonald stresses that, as a group, they are as well adjusted as other children. "Probably of greater importance than the child's cleft in determining his emotional adjustment is the way in which his parents work out their own feeling toward it. An understanding of these feelings—their beginning and how they grow —will help parents direct their feelings into wholesome channels."

Dr. McDonald is a past president of the American Association for Cleft Palate Rehabilitation and a member of the professional advisory committee of both the National and Pennsylvania Societies for Crippled Children and Adults. He is widely known as an authoritative speaker and is the author of many articles and books on speech and hearing.

Copies of "Bright Promise" at 25 cents each may be secured by writing the Publications Office, National Society for Crippled Children and Adults, 2023 W. Ogden Ave., Chicago 12, Illinois.

WIND CHILL

The Army Surgeon General's Office has issued revised instructions for use with its Wind Chill Table, first published in November, 1958, to provide information on the effect of cold temperatures and wind on military personnel.

The revision clarifies the term "wind chill" to mean the *rate of cooling* which occurs when exposed or inadequately protected flesh is subjected to certain temperatures and wind speeds.

The Wind Chill Table, originally based on studies made at the U. S. Army Medical Research Laboratory, Ft. Knox, Kentucky, provides the unit commander, having the temperature and wind speed forecasts, with a ready means of computing the temperature equivalent against which he must protect his men. With these data he can reduce the incidence of cold injuries among troops during cold weather.

The table shows, for example, that if the temperature is expected to be 35 degrees Fahrenheit and the expected wind velocity is about 20 miles per hour, the *rate of cooling* of all exposed flesh is the same as at 38 degrees below zero with no wind.

The new instructions state that though equivalent wind chill figures of 23 degrees, 0 degrees or even –40 degrees are below the freezing point of water, this does not mean that all exposed flesh will freeze solid or that even the surface will be frozen. On the other hand, all unprotected flesh exposed to actual temperatures below 20 degrees F. regardless of wind speed, may freeze.

Exposure to temperatures between 50 degrees and 20 degrees F. may result in cold injury of a type less severe than actual freezing. Examples are chilblains, trench foot, and immersion foot.

The wind chill table and revised directions for its use are being published in DA Circular 40-47, dated 31 December 1959.

Although the revised information provided in the circular is not considered to be complete, it is the best currently available. Continuing research is being conducted by various military and civilian research agencies; and the results of their findings will be available in the near future.

WIND CHILL

Table of Equivalent Temperatures on Exposed Flesh at Varying Wind Velocity

Wind Velocity (miles per hour)										
45	35	25	20	15	10	5	3	2	1	0
90°	89.5°	89°	88.5°	88°	88.75°	87.5°	87°	86°	84.5°	83°
82°	81	80.5	80	79.5	78	76	74	72.5	70	60
72°	71	69.5	68	67	65	60	57	53.5	47.5	23
63°	61	59	57	55	52	44.5	39	34.5	20	–11
51°	49	47	45	42.5	38	28	18.5	11	0	–27
41°	39	36	34	30.5	25	11	0	–9	–23.5	–38
									Below	Below
30°	28	25	23	18	11	–5	–16.5	–40	–40	–40
								Below		
20°	18	14	11	6	–2	–19	–40	–40	do	do
							Below			
10°	7.5	3	0	–6	–15	–35	–40	do	do	do
						Below				
0°	–2.5	–8	–12	–18	–29	–40	do	do	do	do
					Below					
–11°	–14	–18	–23	–30	–40	do	do	do	do	do
				Below						
–21	–24	–30	–35	–40	do	do	do	do	do	do
–32°	–35	–40	–40	....	....	....	do	do	do	....

INSTRUCTIONS FOR USE OF THE TABLE

1. First obtain the temperature and wind velocity forecast data.
2. Locate the number at the top corresponding to the expected wind speed (or the number closest to this).
3. Read down this column until the number corresponding to the expected temperature (or the number closest to this) is reached.
4. From this point follow across to the right on the same line until the last number is reached under the column marked zero (0) wind speed.
5. This is the equivalent temperature reading. Example: weather information gives the expected temperature (at a given time, such as midnight) to be 35° F. and the expected wind speed (at the same time, midnight) to be 20 miles per hour (mph). Locate the 20 mph column at the top, follow down this column to the number nearest to 35° F. The nearest number is 34° F. From this point, move all the way to the right on the same line and find the last number, which is –38° F. This means that with a temperature of 35° F. and a wind of 20 mph, the *rate of cooling* of all exposed flesh is the same as –38° F. with no wind.

President's Letter

THE PHYSICIAN AND ORGANIZED MEDICINE

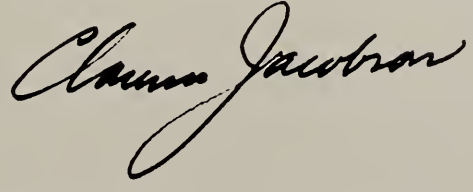
History of medicine from the earliest times to the present constantly recognizes the special nature of the relationship of physicians to one another and to their patients. Free exchange of knowledge among the early physicians served to set them apart from the charlatans and quacks of the period.

Constant concern for the patients' welfare motivated the physicians of the pre-revolutionary period in this country to organize. The first medical societies were founded in Boston in 1735, in New York City in 1749, in Philadelphia in 1765, and in New York again about 1769. The American Medical Society in Philadelphia in 1773, others in New Jersey, 1766; Massachusetts, 1781; South Carolina, 1789; Delaware, 1789; New Hampshire, 1791; Connecticut, 1792; Maryland, 1798; and in Minnesota in 1853.

The societies of New Jersey, Massachusetts and Philadelphia began early to issue records and transactions of their meetings.

Recognition of the necessity for a strong, active national organization came to fulfillment after years of effort in 1847, when the American Medical Association came into being for the purpose of promoting the science and art of medicine and the betterment of public health. The AMA serves a truly democratic organization acting through the House of Delegates, who represent the constituent state associations. At the present time, additional delegates are selected by the Sections of Scientific Assembly and of delegates from the Medical Department of the U. S. Army, Navy, Air Force, Public Health Service and the Veterans Administration. These appointments are made by the Surgeon General or Chief Medical Director of the respective services. Each delegate to the national organization (AMA) represents 1,000 active members or fraction thereof in his state. Thus, Minnesota with its 3,379 active members, has four delegates elected by the House of Delegates of the State Association.

Our State Association and its structures are well known to the membership. Each State Association has similar constitutions with variations to fit local desires and conditions.



Minnesota has thirty-three county medical societies. These county medical societies continue to be the activating element in our State and National organization. Here the individual physician can propose, protest or condemn. He is never denied a voice in the proceedings. His cause, meeting the approval of his fellow members, can be carried to the State House of Delegates or the Council and on to the floor of the House of Delegates of the AMA by the instructed State delegation.

The Council of the state organization, elected by the House of Delegates, meets during the interim between the sessions of the House of Delegates. Members of

the Council are authorized to perform all actions and functions which the House of Delegates might do or perform. Councilors are often called on short notice to meet situations and to act if necessary on problems and proposals which may arise and demand prompt attention. These are a dedicated group of men. Many travel long distances, often disregarding important personal obligations. The agenda during these week-end meetings may include a request for approval of new undertakings by related medical and lay groups, individuals, local and state governmental agencies, also proposals or complaints with medical aspects. Consideration of these items is frequently far-reaching and searching. Organized medicine in our state and nation continues to enable the doctor to render his patient medical care according to standards which are constantly a challenge to his abilities. We all know of the forces which wish to appropriate themselves these privileges to enhance their political or financial stature. To prevail is our objective. Our continued efforts to prevent exploitation of medical ideals demand careful scrutiny of changing economic and social movements so often presented in attractive legislative proposals, i.e., the Forand Bill. Determination to resolve intelligently dissention will enable the profession to render the patient service which from time immemorial has been its privilege and duty to perform. Free professional competition, enabling the patient to choose his own doctor or groups of doctors, is a right which, if denied, will mark the beginning of decline in the quality of medical care. Exploitation of both doctors and patients will follow as witnessed in areas and countries where the special nature of the relationship of the physicians to one another and their patients has been abandoned for politically inspired socio-economic measures.

A physician may enjoy an increased measure of security by virtue of membership in the state association through additional services rendered him. These benefits include an insurance program which approaches complete coverage for the doctor and his family. The professional liability portion of this insurance program has been eminently successful. Diligent work by the appointed committees involved has resulted in giving a maximum coverage for a reasonable premium. Other advantages afforded through the county medical society, Minnesota State Medical Association and the AMA are the twenty-three scientific and twenty non-scientific committees of the Association. These committees are intended to enhance the stature and ability of the Association. Reports of the committees are presented by the respective chairmen at the annual meeting. Contents of these reports often reveal the scope and interest of organized medicine in the welfare of the public they serve.

We can truthfully say organized medicine came into being for an eminently useful purpose; community welfare, community health, and scientific education. It will continue to work effectively to maintain the freedom so necessary for accomplishing these ends.

President, Minnesota State Medical Association

Civil Defense News

CARL WALDRON, M.D., D.D.S., *Chairman, Civil Defense and Disaster Committee, Minnesota State Medical Association*

M. D. TYSON, *Civil Defense Co-ordinator, Minnesota State Department of Health*

Pursuant to a contract dated July 26, 1957, between the United States Government and the American Medical Association, the AMA agreed to "develop and recommend the planning, training and operational organization needed as a basis for a National Emergency Medical Care Plan for the treatment and care of casualties and non-casualties prior to, during and after a hypothetical 20 megaton ground burst thermonuclear attack upon a selected geographical area or areas in the United States." The contract specifically called for recommendations of the AMA covering six major areas:

1. An organizational plan which would result in the optimum of medical care.
2. The utilization of professional and non-professional personnel of the medical and related professions to carry out the plan.
3. The responsibilities of the medical profession in the pre-attack and post-attack period.
4. Those functions of the medical profession that may properly be delegated and performed by paramedical personnel.
5. The training and education needed by all health personnel, professional and non-professional, so that they may be prepared for operational capability in the event of enemy attack.
6. The post-attack sorting of casualties.

The Minnesota Civil Defense Medical Plan and the St. Paul-Minneapolis Target Area were selected for the study area. The report, dated April 15, 1959, states,

"Among the reasons the Minnesota plan was selected for study were its high quality, thoroughness of preparation and its state of being recently prepared.

"Examination of the Health and Medical portion of the Minnesota Operational Survival Plan does not point the way to any clear-cut plan adaptable to all states. . . . It does, however, give some indication of the tremendous amount of minutia, co-ordination of applied effort and difficult-to-obtain information which must go into the making of a plan. The Minnesota planners should be commended on the results of their effort. However, it should be realized by all concerned that a similar plan would not necessarily be adaptable to any other state.

"A whole blood program is essential to medical planning for the care of mass casualties," and "survival planning must insure that adequate equipment for collecting and administering whole blood is located strategically in accessible but safe areas.

"The role of the medical profession is to prepare its members to cope effectively with the results of a mass attack on the United States and to assist actively in preparing the Nation to withstand such an attack. In the event of a mass attack on this country, the role of the medical profession is to provide to the Nation the highest quality and best organized curative and preventive medical services possible in order that maximum numbers of physically and mentally fit survivors, imbued with high morale and a courageous spirit, are and will become available to assume their share of responsibility in the ensuing national recovery efforts and to participate in concurrent and subsequent combat operations.

"Regardless of other factors, any plan for survival will be of little value without adequate training of personnel who are to execute the plan. A training plan must logically follow its preparation. In event of a massive attack upon the United States or its territories, there will be no time to make plans or to train. Training must be initiated early and conducted constantly. It must cover the subjects of mass casualty and non-casualty care not common to current medical training and practice."

The report includes a comprehensive group of recommendations, principles and organizational plans required to accomplish the planning, training and operational organization needed as a basis for a National Emergency Medical Care Plan, for the Federal Government and the States.

In his letter transmitting the report to Leo A. Hoegh, Director, Office of Civil and Defense Mobilization, Dr. F. J. L. Blasingame, Executive Vice President, American Medical Association, stated:

"The report recommends that a national medical civil defense plan be initiated and co-ordinated at the national level and that the Federal Government assume the primary role of guidance and co-ordination of the total national effort. Such a plan, under current concepts as enunciated in Public Law 606, 85th Congress, which makes civil defense a joint responsibility, would be implemented by the Federal Government, the several states and their political subdivisions. The Association assures you of its continued willingness to co-operate and assist in every way possible in preparing the nation, medically, to survive and recover in the event of enemy attack."

The Michigan State Medical Association has been very active in Civil Defense. In a letter dated September 15, 1958, addressed to the Presidents of the component County Medical Societies, the then President of the MSMA, Dr. H. B. Sweetser, wrote: "The MSMA endorses and will give its full support to the implementation of the State Medical Survival Plan." On January 1, 1959, the MSMA established a separate Committee on Civil Defense and Civilian Disaster. In May, 1959, the Resolution Committee, the Council, and the House of Delegates of the MSMA passed two resolutions:

Resolution Number 1

WHEREAS, in the event of a Civil Defense or Civilian Disaster emergency many lay persons will be needed to provide medical care and public health services, and WHEREAS, lay persons need pre-emergency training,

"PILL BILL" TRIAL ENDS AFTER FOURTEEN WEEKS OF TESTIMONY

The question of whether familiar over-the-counter preparations such as Anacin and Alka Seltzer are true "proprietary" drugs and medicines was a critical issue during the final stages of the significant Minnesota legal battle concerning unregulated sales of drug products by a food chain and a wholesale rack jobber. The trial ended December 16 after fourteen weeks of testimony.

In place of closing arguments, Judge William C. Larson, Hennepin County District Court, Minneapolis, Minnesota, asked opposing counsel to submit summary briefs by January 20.

Testimony by authorities on medicine, pharmaceutical chemistry, and drug manufacturing conflicted sharply with claims concerning "secret" formulas and processes made by officials of major manufacturers of over-the-counter products.

The state, which brought the case on behalf of the Minnesota Pharmacy Board, called expert witnesses in support of its contention that the products cannot be classified as "proprietary" since they can be compounded independently of any special knowledge possessed by the manufacturers.

Referring to the eighteen well-known products involved in the trial, all of which are commonly termed "proprietaries," Dr. Thomas B. Magath, Head of the Section of Clinical Pathology, Mayo Clinic, testified that he could produce identical or similar products in his laboratory, relying only on information supplied by labels and obtained through chemical analysis.

Ole Gisvold, Ph.D., Professor of Pharmaceutical Chemistry at the University of Minnesota College of Pharmacy, said it was possible to make a qualitative and quantitative analysis of all products which would determine the identity and quantity of both their active and inactive ingredients.

Later, an expert on pharmaceutical manufacturing stated that the results of such analyses would enable him to manufacture identical or similar products.

This testimony came from Robert H. Miller, Ph.D., Professor of Pharmaceutical manufacturing at the College of Pharmacy. To corroborate his statement, Doctor Miller produced a number of what he described as "Alka Seltzer type tablets" which he said were compounded by a graduate student at the college. The Court refused to accept the tablets as evidence following vigorous objections by defense counsel.

The defendants, Red Owl, Inc., and Groves-Kelco, Inc., argued that the products they have been selling through unlicensed outlets are free from regulation under a provision of the state law which exempts from control by the Pharmacy Board, harmless, non-habit-forming proprietary drugs and medicines when labeled in accordance with state and federal laws.

The definition of the term "proprietary" and the question of habituation was crucial to both the state and the defense. Testimony by the state's expert witnesses on the possibility of duplicating the eighteen products was directed at this point. The last witness called by the state, Wallace F. White, Ph.D., of the University of Minnesota College of Pharmacy, testified that the products in question had habit-forming properties.

Drug Firm Officials Testified

The defense earlier presented a series of witnesses which included executives, medical consultants, pharmacologists, and chemists associated with the manufacturers of the drugs and medicines figuring in the case. Much of the questioning was directed toward establishing the proprietary character of the products.

Among those testifying on behalf of the defendants were Dr. George L. Woolcott, Medical Consultant to Wallace Laboratories, a Division of the Carter Company, manufacturers of Carters' Little Liver Pills; Dr. Raymond L. Conklin, Medical Director, Miles Laboratories, makers of Alka-Seltzer; Thomas B. Singleton, President of the Murine Company; Bernard T. Kearns, General Manager of the Pinex Company; John Alden, Vice President, Norwich Pharmacal Company, manufacturers of Pepto Bismol; and Stanley I. Clark, Executive Vice President of the Sterling

Drug Company, which manufactures Bromo Seltzer.

The importance of the proprietary question was underlined in the early stages of the trial when a defense witness refused to disclose the quantity of an ingredient contained in one of the products. Under cross-examination, Dr. Frederick G. Cullen, medical consultant to the Proprietary Association, declined to state the amount of potassium bicarbonate used in Murine on the grounds that to do so would be revealing a trade secret.

Judge Larson ruled that Dr. Cullen and other witnesses would not be required to divulge such information.

Medical Experts Called

The State, with the Minnesota Pharmaceutical Association joining in the case as an intervenor, presented extensive testimony by medical authorities, including a number of Mayo Clinic specialists, on the deleterious effects of the ingredients contained in the products involved.

BLUE SHIELD COVERAGE FOR THE AGED PROGRESS NOTED

The nationwide Blue Shield Plans and their sponsoring medical societies have registered outstanding progress in implementing the American Medical Association resolution—passed one year ago calling for development of medical care coverage for the aged by voluntary means, John W. Castellucci, Executive Vice President of the National Association of Blue Shield Plans, said recently in Chicago.

"We have just completed a special survey in order to determine the progress made by Blue Shield Plans since the passage of the AMA resolution last December 4, and the results are most encouraging," Castellucci reported.

"Only eight of the sixty-seven Blue Shield Plans located in the United States, with only two per cent of total Blue Shield membership, have no programs for senior citizens in the works at the present time," he noted.

Castellucci said that the remaining fifty-nine Plans either have special aged programs already being offered in their areas, or have programs in various stages of development.

Specifically, the study conducted by the National Blue Shield Association showed that thirty-two of the Plans, representing more than 50 per cent of total enrollment, have made available nongroup programs for persons over the age of sixty-five. Three Plans, with about 15 per cent of total Blue Shield membership, have programs already approved and ready to be offered as soon as the mechanics of administration are completed. Also, twenty-three additional Plans, covering 30 per cent of total enrollment, have senior citizen programs in various stages of development, and these Plans report that they expect their programs to be in force early in 1960.

Thus, about 98 per cent of the total United States Blue Shield enrollment is in areas where special aged programs are already being offered or are in stages of development, all within a one-year period following passage of the AMA resolution.

Castellucci indicated that in the development of programs for senior citizens, the Plans have followed three general lines of approach: (1) developed new programs designed specifically for persons over sixty-five, (2) effected modifications in existing programs to accommodate enrollees over sixty-five, (3) eliminated age limits on existing non-group programs offered to the general public who are not eligible to join through their place of employment.

Prior to the passage of the AMA resolution, the national Blue Shield organization noted, only a limited number of Plans had special programs for the aged, although all Plans traditionally imposed no age limit on group enrollment and permitted continuation of Blue Shield coverage to all members who had acquired it prior to reaching sixty-five.

"While it is realized that the many and varied problems confronting our senior citizens cannot readily be solved in a short period of time, it is heartwarming to note the significant progress made by Blue Shield Plans throughout the country in the past year in developing programs to meet the special medical needs of persons over sixty-five. In offering these programs Blue Shield, of course, is fully cognizant of the splendid co-operation offered by sponsoring medical societies without whose efforts such significant progress could not have possibly been recorded in twelve short months," Castellucci concluded.

STATUS OF FEDERAL HEALTH LEGISLATION EXPLAINED

A breakfast meeting for legislative key men and women and executive secretaries of the North Central States was held at 7:30 a.m., Sunday, November 22, 1959, at Hotel Leamington, Minne-

apolis, Minnesota, prior to the opening of the North Central Medical Conference.

Principal guest speakers included Ernest B. Howard, M.D., Assistant Executive Vice President, AMA; C. Joseph Stetler, Head of the Law Division and Secretary to the Council on Legislative Activities, AMA; and Leonard W. Larson, M.D., Chairman of the AMA Board of Trustees.

Mr. C. Joseph Stetler, in his address to the group, pointed out what could happen in the Second Session of the 86th Congress with regard to the Forand Bill:

1. The Democrats possibly might adopt the Forand Bill as a party plank. If so, the AMA and the medical profession would lose the support of some of our present Democratic friends.

2. There appears a possibility that the Department of Health, Education and Welfare might soften its position in opposition to the Forand Bill as so firmly and strongly expressed by Mr. Arthur Flemming at the recent Forand Bill hearings. His recently reported comments in the newspapers as to "failure of the administration to come up with an alternative" are disconcerting, to say the least. However, it remains a matter of conjecture as to whether or not Mr. Fleming's remarks were accurately reported, and we are in the process of looking into this matter.

3. The Forand Bill might be amended to hospital "only." This scheme is designed to eliminate physician opposition. It would weaken opposition considerably because people would say "why are the M.D.'s worrying? Their services are not included!" Our opponents hope to deceive those physicians who are not looking ahead as well as deceiving the public and congressmen when it is quite obvious to us that this "hospitalization only" would be just as dangerous as the complete Forand Bill itself as presently constituted.

Congress moves very fast and we have to move fast with it, Mr. Stetler continued. For example, the Forand Bill hearings by the House Ways and Means Committee were called on only ten days' notice. Mr. Stetler commented parenthetically, "and we didn't get any help from the staff of HEW Committee, either." At least twenty-six states by now have had conferences on legislation such as recently conducted by Iowa since the AMA meeting in St. Louis. To the extent they have reached *new* people, they are successful, said Mr. Stetler. Political action at this time is extremely important. Mr. Stetler said we must first of all educate our doctors and the auxiliaries. Next year, when additional hearings on the Forand Bill will undoubtedly be held before the House Ways and Means Committee, the payoff will come. If the doctors are ready then, we hope again to defeat this legislation, but the Congressmen will have to be literally deluged with mail from the local level for success. Mr. Stetler emphasized that the medical profession must widen its influence with other groups for support. Doctor opposition is not enough. He strongly encouraged all physicians to win the support of allies and to become more active at the present time in ascertaining who these allies might be and personally contacting them.

Forand Bill Alternatives

As to alternatives to the Forand Bill, Mr. Stetler asked, are the people who are proposing alternatives talking about (1) legislative alternatives or (2) alternatives for the problems of the aged? Our answer must be there is no legislative alternative for the Forand Bill because government is no answer whatsoever. Private enterprise must be our answer. As to the alternative for the problems of the aged—that is, the real problems—we must strengthen our various private enterprise methods, including specifically voluntary private state and community actions, private insurance and Blue Shield plans. I would add that it might be a good idea to heighten a feeling of family responsibility, perhaps even love and understanding, said Mr. Stetler.

Mr. Stetler emphasized that there are two main points or projects of top priority to be considered by every medical society. These are that (1) each state must analyze its own problems with respect to the real problems of the aged and the political problems, and do something about these problems, and (2) each state must work with *other* groups to be successful in defeating the Forand Bill.

Medical Society Testimony Effective

In closing, Mr. Stetler said he wanted to reiterate that it was the testimony of the twelve state medical societies at the recent hearings on the Forand Bill before the House Ways and Means Committee which had the most effect on the congressmen. The state representatives did a magnificent job and their testimony was presented in a most affirmative and positive manner.

Dr. Ernest B. Howard, Assistant Executive Vice President of the AMA, offered these additional suggestions:

1. Each state must set up a priority of projects and should not "spin its wheels" on a multiplicity of

projects at a time when the defeat of the Forand Bill and political activity by physicians are of paramount importance.

2. Each state should have special congressional district plans for organizing a corps or nucleus of physicians to become extremely active on the Forand Bill and in political and legislative matters. It is impossible, said Dr. Howard, to try and "hit" *every* doctor because every physician will not respond. We must count on a few leaders at the local level.

3. Medical Societies should "go after" leaders of other groups. This is of the highest priority; that is, working with those other groups and obtaining their assistance. Dr. Howard said that such groups as the Farm Bureau and insurance associations, etc., must be approached and activated by leaders in the medical profession. Otherwise, they will remain inactive on the Forand Bill. After all, he said, these groups have many other projects and perhaps to them the Forand Bill might be just one issue out of a hundred on which they are asked to assist. It is, of course, true that state associations of manufacturers, chambers of commerce, and others have been apprised of the Forand Bill by their national groups, but, again, he reiterated that doctors at the state and local level must approach these groups and their state and local leaders if action is to be obtained.

Dr. Howard said that it is also of the highest priority that hospital administrators and trustees be sought out and informed about the Forand Bill, inasmuch as their support is extremely important. "I would suggest that even the hospital auxiliaries be contacted," said Dr. Howard. "Again, I say to you that the support of the hospitals is of the highest priority, particularly if the Forand Bill is amended to 'hospitalization only' next year as is most likely."

Forand Bill Fails to Solve Problems of Aged

Dr. Howard referred to a resolution recently approved by both the American Hospital Association and the American Medical Association and which is to be publicized within the near future. The gist of this resolution is that the Forand Bill does not solve the problem of the *needy* aged and that the community approach to the problem is the more satisfactory answer.

Dr. Howard also gave the group advance notice that the Health Information Foundation, in February of 1960, will issue a report on a scientific sampling or polling of some 1,750 persons, age sixty-five or over, which will clearly corroborate the fact that most of our senior citizens do not need Forand-type legislation. This report to be entitled, "Health Care of the Aged," will literally tear the ground right out from under Mr. Forand's claims that persons of sixty-five or over on a blanket basis are in need of such legislation as he has proposed. Dr. Howard emphasized that physician political action committees are most sorely needed in all states, and it is his hope that every state medical society will encourage the formation of such committees. He reminded those present that such committees should work on the issues rather than on the basis of partisan politics in their support or non-support of candidates.

Referring to the question of a legislative alternative for the Forand Bill, Dr. Howard states strongly that socialistic legislation and government alternatives to private enterprise have already carried us far down the road. He said that at least part of the answer of finding a real rather than a legislative alternative solution to the Forand Bill is to halt inflation. Inflation has destroyed in no small measure the value of the dollar and the resources of the aged.

CIVIL DEFENSE NEWS

(Continued from Page 140)

NOW, THEREFORE BE IT RESOLVED: That the House of Delegates of the Minnesota State Medical Association authorizes and directs the Civil Defense and Civilian Disaster Committee to designate appropriate training programs, and

FURTHER BE IT RESOLVED: That training be accomplished by each county medical society in co-operation with the Civil Defense Area Medical Chief.

Resolution Number 2

WHEREAS, under the Civil Defense Survival Plan established under the authority of the Minnesota Civil Defense Act of 1951, there are five Mobile Support Areas (MSA) and certain target area commands established, and

WHEREAS, the Command Area Medical Chiefs control and co-ordinate the medical care, medical supply, and public health activities in their respective command areas, but the actual performance of these activities is the responsibility of the constituent counties and their municipalities,

NOW, THEREFORE BE IT RESOLVED: That the Minnesota State Medical Association directs that the Command Area Medical Chiefs:

1. Be interested in and with the assistance of deputies, be able to devote the necessary time to Civil Defense and Civilian Disaster.
2. Have the assurance that all members of each county medical society will co-operate to the end that an efficient organization and a sound medical plan, consistent with the State Survival Plan and to include training of lay and professional persons, is developed.
3. Be authorized to establish and maintain, in the interest of Civil Defense and Civilian Disaster, direct contact with the county medical societies in his command area.
4. Have the benefit of a committee of one or more members from each county medical society responsible for Civil Defense and Civilian Disaster.

FURTHER, BE IT RESOLVED: That the Civil Defense and Civilian Disaster Committee of the Minnesota State Medical Association be delegated the responsibility to implement this resolution, and to report annually to the House of Delegates.

Medical Legal Opinion

● *The purpose of this section entitled Medical Legal Opinion is to publish news of recent litigation concerning medical practice as well as to cite past actions and opinions of the Court in medical legal matters as a means of refreshing our knowledge of such procedures.*

Minnesota Laws on Practice of Medicine

SUPREME COURT DECISION ON THE PRACTICE OF MEDICINE

As far back as 1905, the Supreme Court of Minnesota in reviewing a conviction for practicing medicine without a license, referred to the examination of patients as a component part of the practice of medicine. In that case the defendant had been convicted in the District Court at Duluth, Minnesota. On appeal to the Supreme Court of Minnesota, the Supreme Court in affirming the conviction stated: "The question fairly presented to this court for decision is, then, whether the statutory offense consisted merely of prescribing drugs for a fee or of practicing medicine without a license. The act is a beneficial one, and is entitled to a reasonable construction. Its purpose was not, as the counsel for the defendant insists, to merely make prescribing for a fee the offense; so that the defendant could have practiced medicine generally, could have held himself out to the world as a physican and surgeon, *could have examined patients,* and inferentially could have operated upon them as a surgeon for pay, and yet would not have been guilty of a misdemeanor within the meaning of the act. On the contrary, its plain object was to prevent the public wrong of practicing medicine without a license.

(State of Minnesota vs. Oredson—decided Dec 22, 1905—96 Minn. 509—105 NW. Rep. 188)

Again, squarely on the subject of diagnosis, the Supreme Court of Minnesota in 1918 in upholding the conviction of a person for practicing medicine without a license stated: "The science of diagnosing human diseases and human ailments has come to be a distinct branch or department of the medical profession; the diagnostician limiting his efforts to a discovery of the disease or ailment from which a patient may be suffering, its character and location, leaving the treatment thereof to some other physician or surgeon. This is a matter of common knowledge. And it requires no discussion or argument to demonstrate that the physician who thus applies his learning and energies is performing a highly important duty of the profession, and is engaged in the practice thereof, though he prescribes no drug and administers no specific treatment. If a physician so limiting his services is practicing medicine, of which there can be no doubt, then in the case at bar the question whether defendant, in diagnosing the ailment of the person named in the indictment, was likewise engaged was at least a question for the jury. The evidence supports the verdict.

(State of Minnesota vs. Rolph—decided May 17, 1918—140 Minn. 190—167 NW. Rep. 553)

This entire matter was again before the Supreme Court of Minnesota in 1933 in a case from Minneapolis in which the Supreme Court declared illegal a contract between a layman and a licensed doctor of medicine, a pathologist, in which contract the pathologist agreed to furnish the results of urinalyses made for subscribers of a so-called health audit service. In that case the plaintiff brought suit to enjoin the members of the Minnesota State Board of Medical Examiners from interfering with a contract which the plaintiff had with the pathologist. For a fee of $10 per year per person the plaintiff agreed to furnish his subscribers with four urinalyses and a blood pressure test each year. The urine samples were then turned over to the pathologist for examination and report back to the plaintiff. If the analysis showed serious abnormal conditions the plaintiff advised the subscriber to consult with a physician; if the abnormality was slight, the plaintiff advised the subscriber as to proper diet, habits, and exercise, if the report of the pathologist so advised. The plaintiff denied that he was engaged in the practice of healing or medicine. The Supreme Court of Minnesota stated:

"In our opinion, advising the subscribers for a fee as to certain improved habits of diet, exercise, or living, although not accompanied by any medical prescription or treatment, is a violation of section 5717 (Medical Practice Act)."

The Supreme Court further said:

"If Dr. ———— was practicing medicine in what he did and in determining for the planitiff whether the condition of the urine was normal or abnormal, then,

in our opinion, the plaintiff was practicing medicine when he passed on to his subscribers the result of the analysis and the advice of the pathologist. It was as much practicing medicine for the plaintiff to engage Dr. ———— to do this for him as it would have been if had attempted himself to perform these analyses, as he in fact did in the case of the blood pressure tests. To pass on to his subscribers advice as to whether or not the test indicated a normal or abnormal condition, and whether or not the subscriber should consult his physician or be content with the advice which the plaintiff might give in regard to diet, exercise or mode of living, was practicing medicine."

The Supreme Court further stated:

"What the law intends is that the patient shall be the patient of the licensed physician not of a corporation or layman. The obligations and duties of the physician demand no less. There is no place for a middleman."

(Sec. 159.18 Minnesota Statutes)

The Supreme Court emphasized that the Minnesota Basic Science Law included "the diagnosis or analysis of the condition of human health" as being a part of the practice of healing. The Court also held that the contract between the plaintiff and the pathologist was illegal, stating:

"It follows that the contract between the plaintiff and Dr. ———— was in furtherance of plaintiff's violation of these statutes. It was illegal, against public policy and void, and no injunction will lie to prevent interference therewith."

(Granger vs. Adson, et al. decided November 3, 1933—250 NW. 722)

In recent years, the most outstanding case in this field of physician-hospital relations is found in the District Court of the State of Iowa at Des Moines, Iowa. In that case, some thirty-four Iowa hospitals and the Iowa Hospital Association brought a lawsuit against the Iowa State Board of Medical Examiners, the Iowa Association of Pathologists and the Attorney General of Iowa, with the Iowa State Medical Society as an Intervenor in the Lawsuit, "for favorable declaratory relief on the following major issue: whether or not the Plaintiff hospitals are engaged in the illegal corporate practice of medicine in purveying to patients in said hospitals medical services in the form of laboratory procedures and x-ray procedures for compensation." The case was a test case and hundreds of pages of testimony were taken. In fact, the Court heard the case from May 19, 1955, through June 28, 1955, and then again from September 15, 1955, through October 25, 1955, a total of approximately twelve weeks. Arguments of legal counsel were heard by the Court on November 2, 1955, and printed briefs were filed by the parties.

The Court made twenty-two findings of fact and among them, the following:

" 5. The Court finds that pathology and radiology are recognized specialties in the practice of medicine.

"11. The Court further finds that laboratory medicine and radiology in their several branches are indispensable to attending physicians in modern medical care, and that facilities must be available in or near hospitals, and that the ownership and maintenance of laboratory facilities is an integral part of a modern hospital.

"13. The Court finds that when these services are not under actual physician control and supervision, the quality of the services may suffer."

In its conclusions of law, the Court among many others, stated:

"If plaintiffs' contention is right then all institutions included in the definition of 'hospital' set out in Section 135B.1 would have a right to operate pathology and x-ray laboratories and perhaps practice other specialties in the field of medicine."

The Court further stated:

"Most of the reasons given in the decisions condemning corporate practice generally are applicable to the non-profit corporations."

The Court further stated:

"It is the conclusion of the Court that plaintiffs are not entitled to operate pathology and x-ray laboratories merely because they have done so for many years, nor has the Court the right to indulge in judicial legislation."

"It is the conclusion of the Court that under the facts established in this case and the law as the Court understands it, that the work done by the pathologist, radiologist, and the technicians working in the pathology and x-ray laboratories, constitute the practice of medicine."

"That plaintiff hospitals are not excluded from the requirements of the Iowa practice acts in regard to the practice of medicine on the basis that they are non-profit corporations or because of long standing custom and inactivity on the part of those charged with enforcing the law, or because of public policy in the absence of legislative enactment."

"That plaintiff hospitals under the Court's findings of fact and conclusions of law have been engaged in the unauthorized, unlicensed and illegal practice of medicine."

"That under the Court's findings of fact and conclusions of law the pathologists and radiologists have been violating the provisions of Subsection 4 of Section 147.56." (Fee splitting).

Following the above trial, pathology and radiology services in hospitals were transferred from Blue Cross contracts to Blue Shield contracts in the state of Iowa (See pages 506-507, MINNESOTA MEDICINE, July, 1958).

LAST CALL FOR EDITORS OF MINNESOTA MEDICINE

HELP FOR THE ALCOHOLIC —A PROGRESS REPORT

Have you ever thought of your medical society as an extension of your own practice? By sparking civic action, societies can often organize services individual doctors are too busy to give their patients.

The PR Doctor reports the following successful endeavors which could be adapted locally by county medical societies with similar results. The Genesee County (Flint, Michigan) Medical Society, tired of seeing alcoholic patients through the D.T.s only to watch them go right back to the bottle, decided a follow-up service for chronic drinkers was badly needed. So the society's committee on alcoholism got together with a citizens committee and drew up a plan for providing *group therapy to alcoholics as a local hospital service.* State funds were obtained to match hospital funds, a social worker hired, and the Hurley Hospital Department of Group Therapy was established.

Meetings were held twice a day and two nights a week. *All patients admitted to the hospital for alcoholism are required to attend.* Others are referred by doctors or are former hospital patients. Families of drinkers are also uged to attend.

The clinic doesn't try to provide individual counseling, although an afternoon discussion period does give patients a chance to talk about their problems. Primarily the lectures give patients an idea of what alcoholism is and what they face in rehabilitating themselves. Patients are steered toward such groups as Alcoholics Anonymous for fellowship and individualized help.

Living and working with an alcoholic can be a problem in itself. To help families, friends and employers of drinkers form proper attitudes and keep their own peace of mind, the Genesee County Society has published a booklet called "A Happy Solution to the Problem of Alcoholism." The booklet sets down practical pointers on how and how not to treat the alcoholic. It reassures its readers that "if you are serene and hopeful, if you accept the drinking as a symptom, if you keep faith with the drinker's true self . . . if you let him alone to find his own way to recovery . . . if you are ready with information on where to get help when he asks for it, you are doing your part."

COUNTY FAIR HEALTH EXHIBITS ARE ATTENTION GETTERS

County fairs provide an excellent opportunity for medical societies to do an effective job of public health education with a minimum amount of expense. Many county medical groups throughout the United States have found that an attractive display at a county fair receives considerable attention. This is also a project which appeals to members of county medical auxiliaries.

A new catalog of exhibits available through the American Medical Association includes a selection of available exhibits on various medical and health subjects. The catalog has been designed with the idea that it can be kept current with the addition or deletion of exhibit specification sheets as new displays are completed and as older exhibits are discarded.

The exhibits of the Association are designed for viewing by either professional or lay audiences. The suggested audience for each exhibit is indicated on the exhibit specification sheets.

These exhibits are provided to medical societies on a no-charge basis. However, the borrowing organization is asked to pay freight charges both to and from our warehouse in Chicago. Requests from other groups should be made through a state

or county medical society. The approximate cost of shipping an exhibit can be determined by noting the weight listed in the catalog and then contacting a local trucking firm, prefarably one with a direct line to and from Chicago. All shipments from the AMA exhibit warehouse are made prepaid.

The following suggestions are given to expedite your requests for these exhibits:

1. Requests for use of exhibits should be made as far in advance as possible.
2. Requests should be made on the order form enclosed in the catalog, and should be authorized by the secretary or president of a state or county medical society.
3. All requests should be addressed to: American Medical Association, Communications Division, Exhibit Section, 535 North Dearborn Street, Chicago 10, Illinois.
4. Railway Express may be employed when there is a very limited amount of time for shipment; however, this method of transportation is considerably more expensive than motor freight.

Your state association will cooperate in helping interested groups to place orders for these exhibits. A large selection of public health education printed material is also available through the state office for distribution with these exhibits.

FREE PUBLIC HEALTH EDUCATION LITERATURE AVAILABLE

Americans are a reading public. Why not use this opportunity to make informative public health education materials available to your patients in the waiting room? A few of the many AMA booklets and printed health aids prepared by the AMA include:

The Forand Bill . . . and What You Should Know About It
Personal Health Cards
The Healthy Way to . . . Weigh Less
To All My Patients
Do You Like to Make Decisions?
Plastic Film—Correct Use and Mis-Use—Helpful Hints to Parents
The Merchants of Menace
The Fifth Freedom Guarantees You the Physician of Your Choice!
Stay Young—Think Young
Your Family Health Record
Youth is a State of Mind
What's Up With Our Medical Schools?
The Pill That Could Change America—An Up-to-date Review of Socialized Medicine in the World Today (single copies for waiting rooms only).

The materials will be sent to you in quantity without charge. Mail your order to the Minnesota State Medical Association, 496 Lowry Medical Arts Building, St. Paul 2, Minnesota. Sample copies will be sent upon request.

WHAT IS "BEST MEDICAL CARE"?

According to Dr. Malcolm S. Watts of San Francisco, the best medical care embodies the essential elements of medical practice. These include the need of an individual patient for help with a particular problem, the motivation of the physician and his concern with the individual patient, the secure belief of the patient that the physician can and will help, and the tool or technology by which the help is given.

It considers the economic, social and political predicament of the patient in terms of his need for medical care. It insures that the doctor's primary allegiance remains to the patient and that it is not unduly diluted by financial or other responsibilities to collective groups within or without the profession. It provides for freedom of action for both doctor and patient, before and after illness strikes, in order that the patient may derive the physiological benefit and psychological comfort of faith in his medical care. It requires the economic, social and technological availability of competent physicians, ancillary personnel, and adequate facilities for service.

The best medical care must always be vital, dynamic, changing, growing—in response to the American urge for improvements in standard of living.

Most Americans will pay more for better cars, better housing, better food, or better clothing. They can and will pay more for better medical care if they understand its costs and are convinced of its benefits.

Minnesota Medical Services, Inc. (Blue Shield)

Dr. Richard R. Cranmer, Minneapolis, Acting Executive Director of Minnesota Medical Service Inc. (Blue Shield) since the death of Dr. Edwin J. Simons, has been named Executive Director according to an announcement by Dr. C. A. McKinlay, President. The appointment took place at the meeting of the Board of Directors in Minneapolis, December 30, 1959.

Following the Blue Cross action terminating its working agreement with Blue Shield, Dr. Cranmer has directed the program the centralizing all services and operations within the Blue Shield organization.

With Dr. O. I. Sohlberg, a member of the Minnesota Blue Shield Board of Directors since 1947 Dr. Cranmer has among the earliest advocates of a voluntary, prepayment medical care plan in Minnesota.

Speaking of his association with Dr. Sohlberg Dr. Cranmer remarked: "For years I believed mine was a lone voice in urging the development of such a plan. Then, about 1944, I unexpectedly discovered I had a staunch ally in Dr. Sohlberg." Unknown to each other, the two physicians had been working toward the same goal. Dr. Sohlberg carrying on his activities in St. Paul, Dr. Cranmer in Minneapolis.

In 1944. at the annual meeting of the State Medical Association held in Rochester, Dr. Cranmer introduced to the House of Delegates the first motion calling for the establishment of a Blue Shield Plan in Minnesota. It was unanimouslv passed.

Leadership provided by Drs. Cranmer and Sohlberg played a major role in the movement which finally resulted in passage of the 1945 enabling act authorizing organization of a voluntary prepayment plan to cover medical services.

Dr. Cranmer has held a succession of important posts in the Blue Shield Plan since its beginning in Minnesota. From 1950 to 1952, he served on the Executive Committee of the Associated Blue Shield Plans, a national body made up of representatives of state organizations. He was Vice President of the Minnesota Blue Shield Board from 1947 to 1955 and President from 1956 to 1959 when he assumed the post of Acting Executive Director. During the years 1948 to 1949, he served on the Board of the Blue Cross hospital plan.

Speaking of the continuing Blue Shield program Dr. Cranmer stated:

"Through the new Division of Enrollment and Service, Blue Shield will be in direct contact with subscribers. Representatives of the division, living in the communities where they serve, will enable us to establish closer liaison with participating doctors, as well as subscribers."

"As always," he continued, "the Blue Shield organization will maintain a close relationship with county medical societies and other professional groups throughout the State. It is hoped that expanded personnel will permit the executive staff to devote even more time to this vitally important function."

In January, Dr. Cranmer reported, the St. Louis Ramsey, Washington and Clay-Becker county medical societies adopted resolutions endorsing Blue Shield's program of extending benefits to cover more medical services rendered by doctors. "These expressions of confidence are further evidence that the addition of coverage for diagnostic x-ray and laboratory services was a wise and welcome decision," he said.

Dr. Cranmer also stated that one of his first actions when the current reorganization is completed will be to recommend consideration of increases in certain areas of the Blue Shield Fee Schedule.

Commenting on the recent separation from Blue Cross, Dr. Cranmer said:

"The present turning point came as the result of Blue Shield's refusal to compromise the highest principles of the medical profession and because of the desire to bring greater benefits to subscribers. Surely, the determination to follow such a course can only lead to the fuller realization of Blue Shield's goals."

HEALTH SCHOLARSHIPS ANNOUNCED FOR 1960

The National Foundation Health Scholarship Program is offering 103 health scholarships for four years of study at fully-accredited schools of medicine. To be eligible, a student must be currently enrolled as an undergraduate at an accredited college and must be accepted for admission to medical school for the fall of 1960 by the applications deadline of April 1, 1960. The only obligation of Health Scholarship winners is to have the intention of completing their education and of serving the health field as a member of their chosen profession.

Purpose.—Health scholarships are four-year college scholarships. They pay $500 a year, or a total of $2,000. Each is to help a student prepare for a career as a nurse, an occupational therapist, a physical therapist, a medical social worker, or a doctor. A minimum of 515 health scholarships are offered annually.

Availability.—To be eligible, an applicant must be a citizen of the United States and: (a) a graduating high-school senior interested in a career in *nursing, occupational therapy* or *physical therapy;* or (b) a college sophomore aiming for a career in *medical social work;* or (c) a college undergraduate accepted for admission to an approved school of *medicine.*

In 1960, awards will be made only to students who have been accepted for admission to an accredited college or university for the academic year 1960-61. Students may file applications for scholarships pending acceptance for admission to an accredited school.

Winners are selected on the basis of academic record, personal qualifications, professional promise and financial need, as shown in the application blank and other credentials submitted by or on behalf of each applicant. Winners of these awards are announced during the summer.

Renewal.—Health scholarships are renewed annually for no more than three additional years, or for a total of four consecutive years, provided the student is in good standing and is following the educational program approved.

Use of Funds: Health scholarship funds may be used for any educational expense. Students may accept scholarships from other sources, but are expected to inform The National Foundation of the source and amount of other awards.

Nation's Leading Designers and Builders of prefab "Medical Buildings"

An Erdman prefabricated medical building

• *designed to insure efficiency*

An efficient suite for medical use is not just a group of rooms. It has to be engineered to make the best use of space. Erdman prefabricated medical offices are individually designed for the selected building site and with your specific needs in mind, just as we have done for more than 275 doctors throughout the country.

• *prefabricated to save money*

Because of standardized plans, mass-produced parts and materials, and experienced craftsmen — Erdman saves much in costs, minimizes construction time and insures an ideal building.

If you are interested in a medical building, write Marshall Erdman and Associates, Inc., 5117 University Ave., Madison 5, Wisconsin.

Wesson satisfies the most exacting appetites

To be effective, a diet must be *eaten* by the patient. The majority of housewives prefer Wesson particularly by the criteria of odor, flavor (blandness), and lightness of color. (Substantiated by sales leadership for 59 years and reconfirmed by recent tests against next leading brand with identification removed, among a national probability sample).

WESSON'S IMPORTANT INGREDIENTS:

Wesson is 100% cottonseed oil... winterized and of selected quality

Linoleic acid glycerides	**50% to 55%**
Phytosterol (predominantly beta sitosterol)	**0.4% to 0.7%**
Total tocopherols	**0.09% to 0.12%**

Never hydrogenated — completely salt free

Each pint of Wesson contains 437-524 Int. Units of Vitamin E.

FREE *Wesson recipes, available in quantity for your patients, show how to prepare meats, seafoods, vegetables, salads and desserts with poly-unsaturated vegetable oil. Write—specifying quantity needed—to The Wesson People, 210 Baronne St., New Orleans. La.*

The diet prescribed to lower cholesterol can include a breakfast egg cooked in poly-unsaturated Wesson.

HEALTH SCHOLARSHIPS

(Continued from Page A-60)

Application blanks and detailed information are available from: (a) the head (or guidance or scholarship official) of your high school or college; (b) your local chapter of The National Foundation or (c) The National Foundation Health Scholarships, 800 Second Avenue, New York 17, New York.

Completed scholarship application and all other required credentials must reach The National Foundation Health Scholarships Office by April 1, 1960.

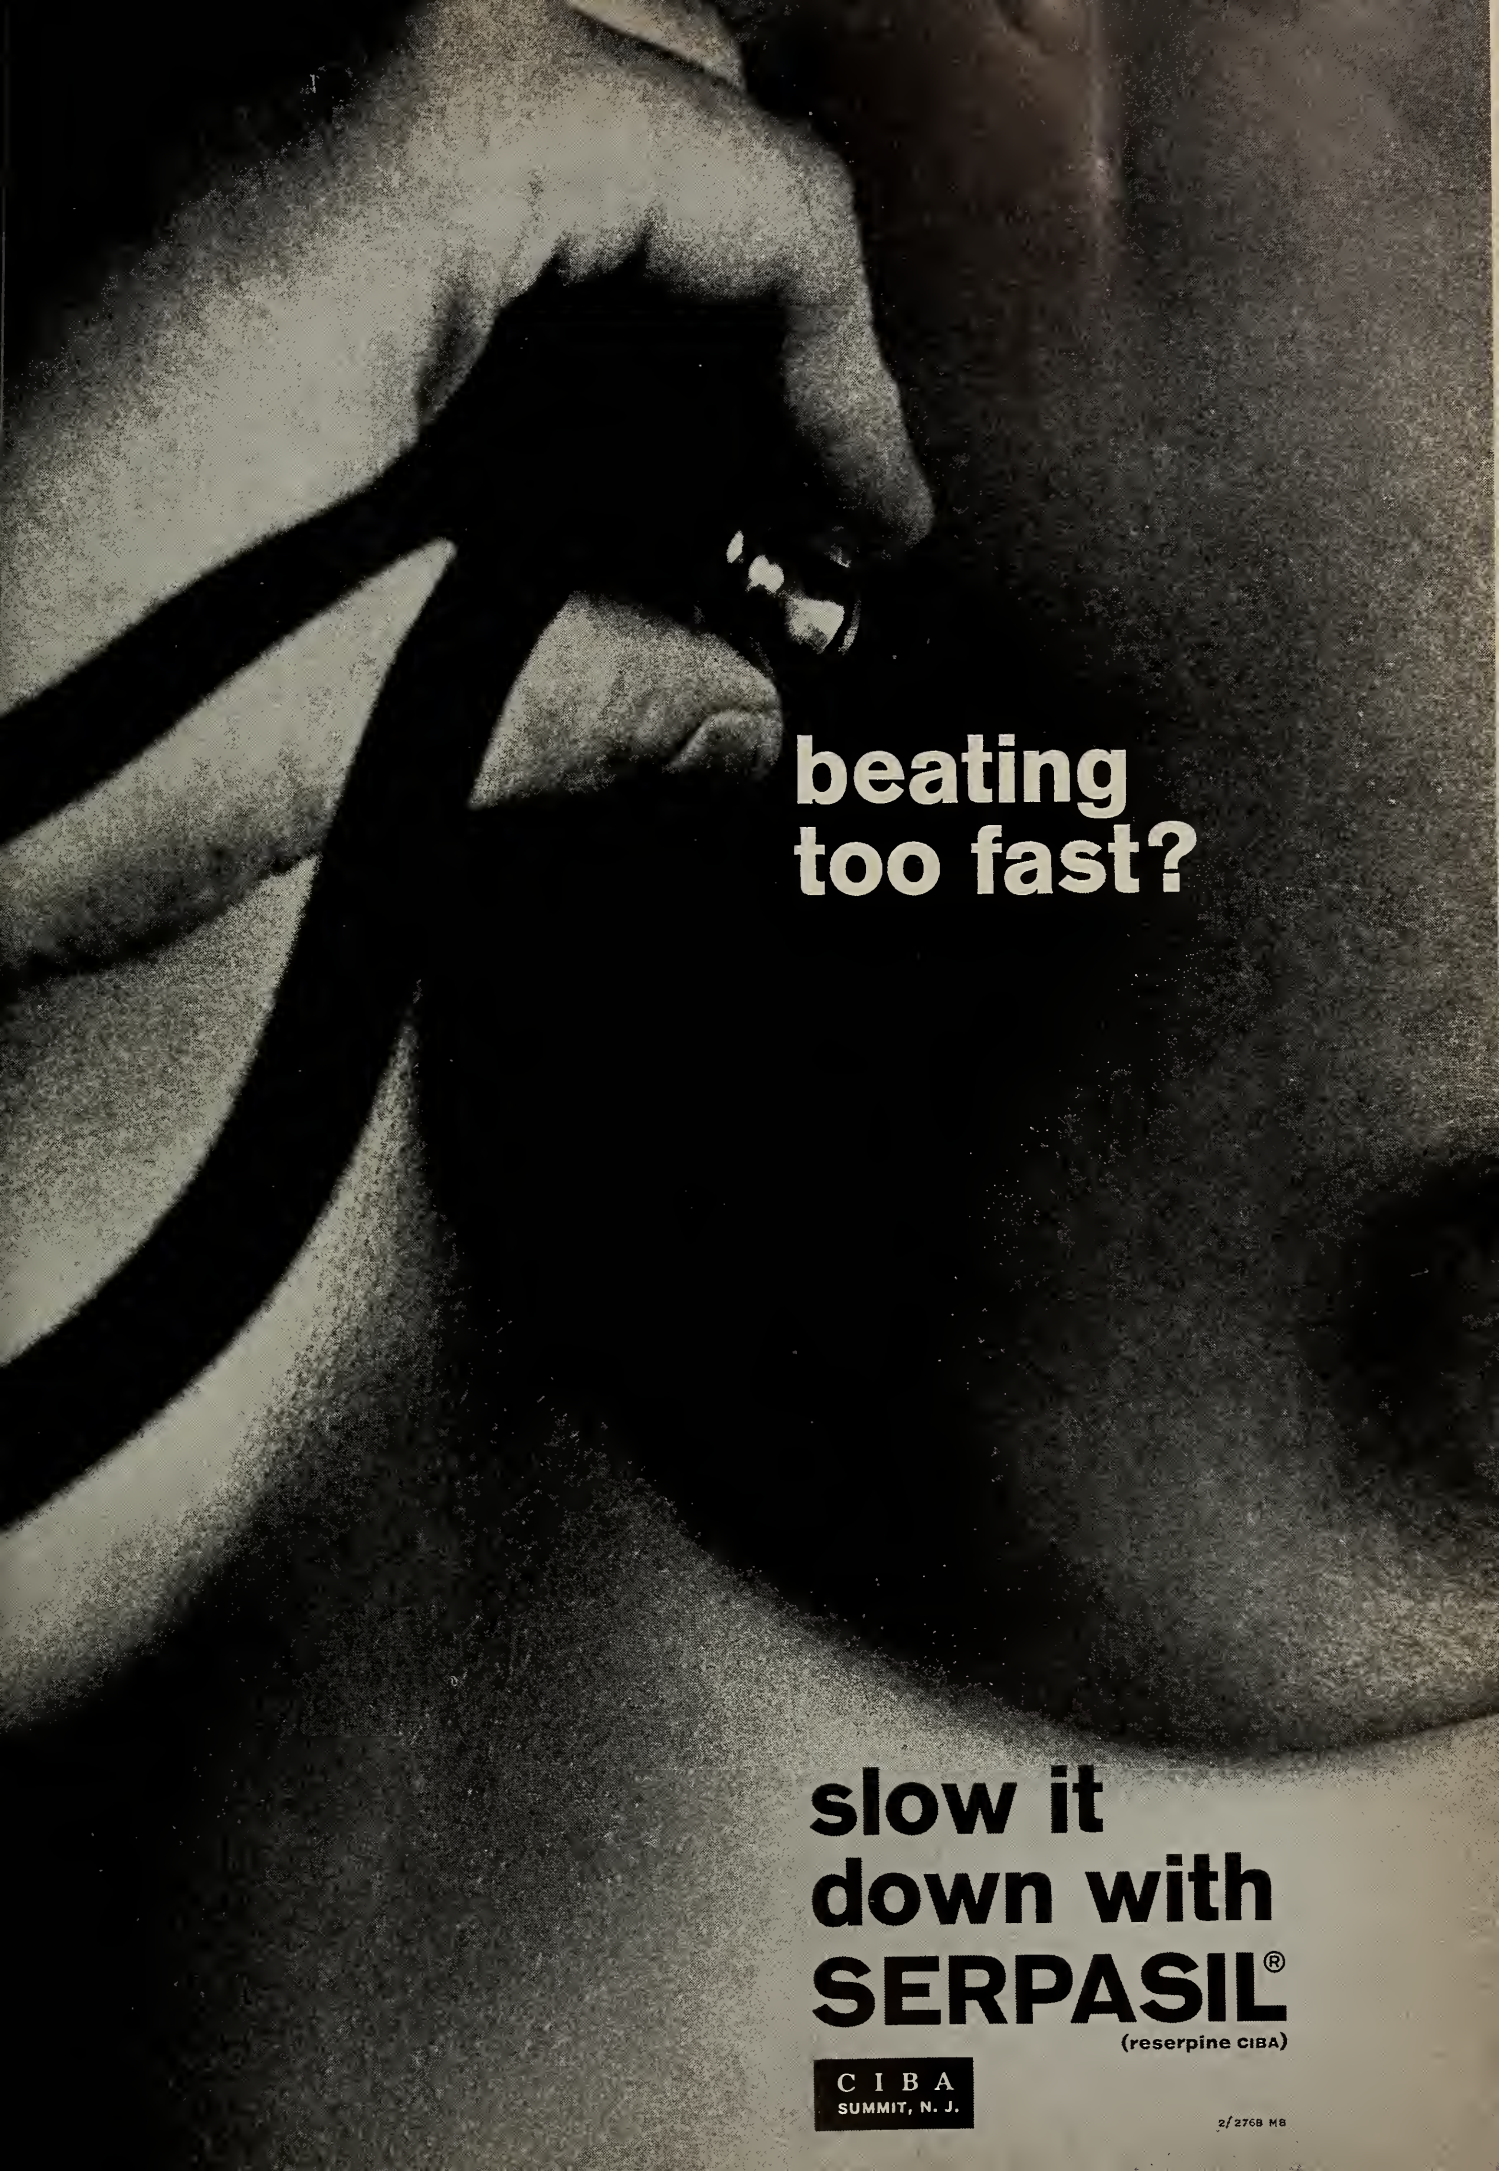
BLOOD BANK TRAINING COURSES

Classes for laboratory personnel in theory and procedures for blood banking will be given again this year by the Minnesota Civil Defense and Disaster Blood Program. Four different dates have been selected for the five-day courses which will be given at the Minneapolis War Memorial Blood Bank, Minneapolis, on April 18, June 27, September 12, and December 5.

The course will include discussions of human red cell antigens, the Rh-Hr system, problems in establishing an emergency donor system, sources of error and use of controls, and techniques for collecting blood from donors. During the five days, students will also have an opportunity to observe the interview and examination of donors, prepare the arm for phlebotomy, and gain a working knowledge of the physical equipment used in bleeding donors.

This training is considered invaluable in the event of man-made or natural disaster when considerable amounts of whole blood are needed, as well as in more normal periods because of the frequent use now made of blood banks.

Each of the courses will be limited to eight students. Tuition for the course is $40.00, half of which will be paid by the Office of Civilian and Defense Mobilization. Additional information and application blanks can be obtained from Mrs. Helen Arndt, M.T. (ASCP), Minneapolis War Memorial Blood Bank, 2304 Park Avenue, Minneapolis.



MAYO CLINICAL REVIEWS ANNOUNCED

Staff members of the Mayo Clinic and the Mayo Foundation for Medical Education and Research will present a three-day program of lectures and discussions on problems of current interest in general medicine and surgery, April 4, 5, and 6, 1960.

The American Academy of General Practice and the College of General Practice of Canada have informed the Committee on Clinical Reviews that up to twenty-one hours of Category I credit may be obtained by members of the American Academy of General Practice or the College of General Practice of Canada attending.

There are no fees for this program.

The number of physicians who can be accommodated is necessarily limited. Those wishing to attend should communicate with the Clinical Reviews Committee, Mayo Clinic, Rochester, Minnesota.

Woman's Auxiliary

RAMSEY COUNTY REPORTS JANUARY ACTIVITIES

The Ramsey County Auxiliary held its Board meeting on January 11, 1960, after the holiday recess. Mrs. Hanns Schwyzer, President, called the meeting to order. Plans were formulated for the informal dinner dance which was given for members and their husbands at the Town and County Club. Mrs. Rodney Sturley and other members of the committee are to be congratulated on their efforts in making the evening a pleasant one.

Mrs. John R. Meade, Health Council Representative, attended a recent meeting of the Council. Red Cross activities, including the blood donor system, were explained to the members. Auxiliary members have chosen the blood bank project as the principal project of the year.

Mrs. William F. Menold and Mrs. Frank Ubel have represented the Auxiliary at Inter-Club Council meetings. In this way, the Ramsey County Auxiliary maintains a close contact with the work of other civic organizations in St. Paul.

Mrs. Wallace Gleason, Mrs. Harold O. Peterson and Mrs. Earl Wetzel are busy contacting public and private schools to give information concerning the Association of American Physicians and Surgeons' Essay Contest.

STATE AUXILIARY PARTICIPATES IN ANNUAL TUBERCULOSIS SPEAKING PROJECT

Ten Minnesota Junior and Senior high school students won awards in the twenty-ninth annual Christmas radio speaking project aimed at informing teenagers of today's tuberculosis problems and ways of preventing the disease.

Trophies were presented by the Woman's Auxiliary to the Minnesota State Medical Association, which co-sponsored the project with the Minnesota Tuberculosis and Health Association and WCCO radio.

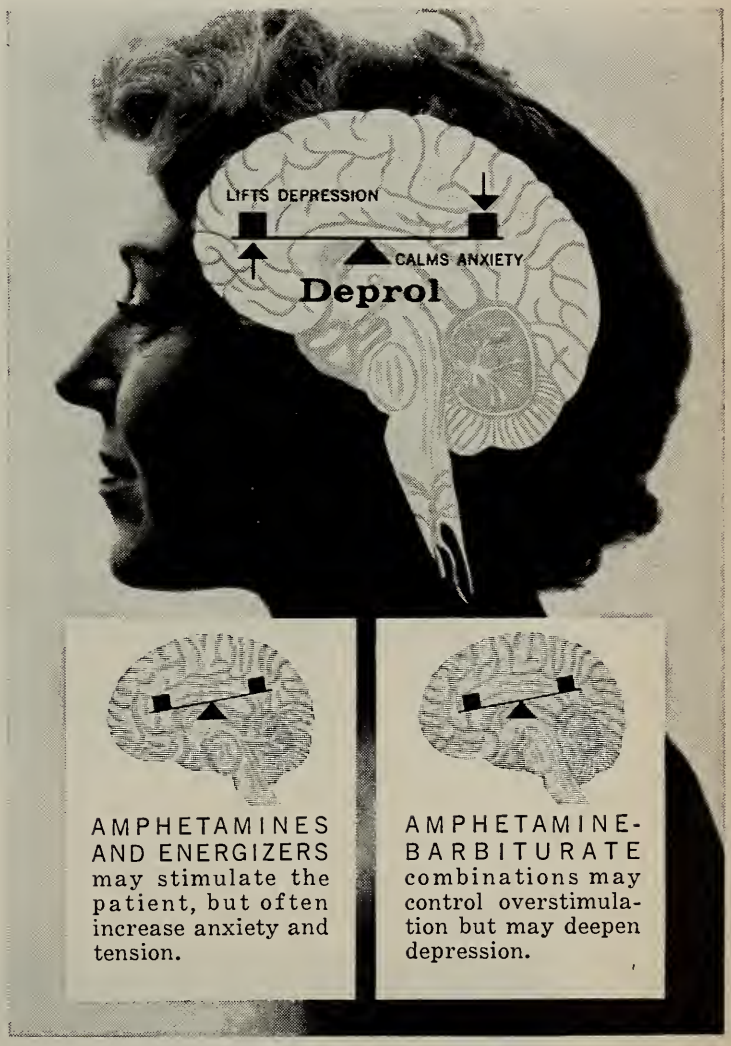
Winners, who broadcast their scripts over WCCO December 13 and 20, are as follows:

Junior High Students—Janet Huibregtse, South Junior high school, Hopkins, first; Helen Cuddy, Our Lady of Good Counsel Academy, Mankato, second; Cynthia Reardon, Visitation Convent, St. Paul, and Susan Zeiher, St. Mary's School, Morris, runners-up.

Senior High Students—Margo Meyer, St. Felix high school, Wabasha, first; Stanley Spangenberg, Fairmont

(Continued on Page A-72)

as it calms anxiety!



Smooth, balanced action lifts depression as it calms anxiety... swiftly and safely

Balances the mood – no "seesaw" effect of amphetamine-barbiturates and energizers. While amphetamines and energizers may stimulate the patient – *they often aggravate anxiety and tension.* And although amphetamine-barbiturate combinations may counteract excessive stimulation – *they often deepen depression.*

In contrast to such "seesaw" effects, Deprol lifts depression as it calms anxiety – both at the same time.

Acts swiftly – the patient often feels better within a few days. Unlike the delayed action of other drugs which may take two to six weeks to bring results, Deprol's smooth, immediate action relieves the patient quickly – often within a few days.

Acts safely – no danger of liver damage. Deprol does not produce liver damage, hypotension, psychotic reactions or changes in sexual function – frequently reported with other drugs.

BIBLIOGRAPHY *(10 clinical studies, 714 patients):*

1. Alexander, L. (35 patients): Chemotherapy of depression – Use of meprobamate combined with benactyzine (2-diethylaminoethyl benzilate) hydrochloride. J.A.M.A. 166:1019, March 1, 1958. **2.** Bateman, J. C. and Carlton, H. M. (50 patients): Meprobamate and benactyzine hydrochloride (Deprol) as adjunctive therapy for patients with advanced cancer. Antibiotic Med. & Clin. Therapy 6:648, Nov. 1959. **3.** Bell, J. L., Tauber, H., Santy, A. and Pulito, F. (77 patients): Treatment of depressive states in office practice. Dis. Nerv. System 20:263, June 1959. **4.** Breitner, C. (31 patients): On mental depressions. Dis. Nerv. System 20:142, (Section Two), May 1959. **5.** McClure, C. W., Papas, P. N., Speare, G. S., Palmer, E., Slattery, J. J., Konefal, S. H., Henken, B. S., Wood, C. A. and Ceresia, G. B. (128 patients): Treatment of depression—New technics and therapy. Am. Pract. & Digest Treat. 10:1525, Sept. 1959. **6.** Pennington, V. M. (135 patients): Meprobamate-benactyzine (Deprol) in the treatment of chronic brain syndrome, schizophrenia and senility. J. Am. Geriatrics Soc. 7:656, Aug. 1959. **7.** Rickels, K. and Ewing, J. H. (35 patients): Deprol in depressive conditions. Dis. Nerv. System 20:364, (Section One), Aug. 1959. **8.** Ruchwarger, A. (87 patients): Use of Deprol (meprobamate combined with benactyzine hydrochloride) in the office treatment of depression. M. Ann. District of Columbia 28:438, Aug. 1959. **9.** Settel, E. (52 patients): Treatment of depression in the elderly with a meprobamate-benactyzine hydrochloride combination. Antibiotic Med. & Clin. Therapy. In press, 1959. **10.** Splitter, S. R. (84 patients): The care of the anxious and the depressed. Submitted for publication, 1959.

Dosage: Usual starting dose is 1 tablet q.i.d. When necessary, this may be gradually increased up to 3 tablets q.i.d.

Composition: 1 mg. 2-diethylaminoethyl benzilate hydrochloride (benactyzine HCl) and 400 mg. meprobamate.

Supplied: Bottles of 50 light-pink, scored tablets. Write for literature and samples.

high school, Fairmont, second; Jeannine Jansen, Father Pierz Memorial high school, Pierz; and Cindy Ivins, Priscilla Lovestedt and Kathleen Rowland, all of John Marshall high school, Rochester, runners-up.

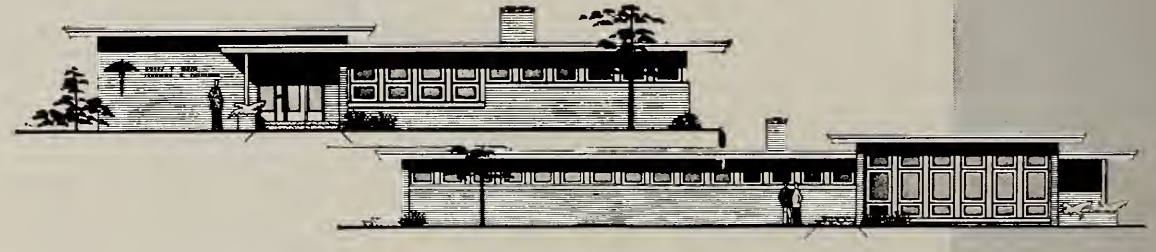
Honorable mention was given the following:

Senior High Students—Nicole Rath, Karon Schmitt and Rita Mattingly, Our Lady of Good Counsel Academy, Mankato; Rita Hollerman, St. Benedict's high school, St. Joseph; Beverly Rossini, St. Agnes high school, St. Paul; Fidelia Nilles, Mount St. Benedict Academy, Crookston; Kathy Peterson, Blooming Prairie high school, Blooming Prairie; Joyce Swanke, Olivia high school, Olivia; Linda Sandberg, Alango high school, Angora; and Edwina Grajeck and Gretchen Schneider, Convent of the Visitation, St. Paul.

Junior High Students—Linda Whitney and Darlene Worlie, Roosevelt Junior high school, St. Paul; Margie Kippley, St. Mary's School, Worthington; Mary Knutson, Convent of the Visitation, St. Paul; Kathryn Koehl, Stevens School, Hancock; and Ellen Becker, St. Michael's School, Mahnomen.

MARITAL STATUS OF GRADUATING MEDICAL STUDENTS

Preliminary evidence, based on a questionnaire survey of the financial problems of medical students addressed to members of the graduating class of 1959, shows that the family composition of medical school graduates has changed over the last few years. To date, information has been tabulated for 4,400 male students, of whom 2,284 were married. Comparisons have been made with a survey conducted by the National Opinion Research Center on a small sample of the graduating class of 1956. This study of 1959 graduates shows 63 per cent married, versus 55 per cent in the 1956 N.O.R.C. study, and of the married students 24 per cent had two or more children in contrast with 12 per cent of the earlier study. (Seven per cent of the 1959 class reported having three or more children. One graduating senior reported having seven!)



Information obtained from 232 female medical students in the class of 1959 shows that 58 per cent were single and 40 per cent were married. Thirty-three per cent of the married women had one or more children.

KNOWLEDGE AND WISDOM

The fault of the quiz programs was not so much that some of them were "rigged" but that they helped perpetuate a false idea of what knowledge and education are.

Dag Hammarskjold said recently that in modern times we are in danger of taking facts for knowledge, and knowledge for wisdom.—Michael Reck, *New York Times.*

Communications

FOREIGN FELLOWSHIPS FOR MEDICAL STUDENTS

A program to further international relations for the United States by making it possible for medical students to serve as unofficial ambassadors, has been announced by the Association of American Medical Colleges and Smith Kline & French Pharmaceutical Company.

Established by a $180,000 grant from Smith Kline & French, the new program will provide foreign fellowships through which students of United States medical colleges may travel abroad for a limited period of time to work in remote areas of the world.

These fellowships will provide selected medical students with broad clinical experience, an understanding of preventive medicine as practiced abroad, an opportunity to study diseases not common to the United States and a definite awareness of the acute need for American physicians and their medical knowledge abroad. In addition, this opportunity will afford the selected Fellow the chance to play the role of individual ambassador or missionary. He will be representative of the method of medical education in the United States today while communicating the most recent information available on medical science to distant areas of the world.

Any student who has completed his third year of medical school is eligible to apply for a fellowship. If accepted, he may spend twelve weeks or more at a foreign mission or other remote private medical facility, or a public health unit, clinic or hospital.

The award of a fellowship will be determined on the basis of the applicant's ability, potential and his objectives in wanting to study abroad. Emphasis will be placed on the applicant's plan for study and experiences which would not be afforded to the applicant at a medical school here in the United States and through which the student will bring back significant knowledge to the United States.

Cash awards will be made on an individual basis. A contribution to the expenses of the wife or husband accompanying the Fellow will be made when this seems desirable in terms of the objectives of the program and of the Fellowship. No awards will be made for the expense of children.

At the termination of time spent abroad, a Fellow is expected to write a report summarizing his clinical experiences abroad, including his personal evaluation of the effectiveness of the trip as a part of his medical education.

Medical students who wish to apply for a fellowship must submit their application to the dean of their medical school. If the application is acceptable, the dean will then endorse it and forward it to the Selection Committee at the Association of American Medical Colleges.

INFLUENZA EPIDEMICS

Outbreaks of influenza-like disease have been officially reported in fourteen States and the District of Columbia, according to a report by Surgeon General Leroy E. Burney of the Public Health Service.

In seven States and the District of Columbia, laboratory tests have identified the disease to be the A-2 or Asian strain. Isolations have not been completed in the remaining seven States.

No estimate can be made at this time of the numbers of persons stricken on a nationwide basis, Dr. Burney said. Reports from State Health Officers, however, indicate that the extent varies from small groups such as university students to widespread areas such as sections of entire cities.

This Section is for you to voice your convictions, comments, and queries on all subjects political, economic, historic, humorous, scientific or otherwise, to many physicians. Writings not sufficiently formal and too brief for an editorial or a scientific manuscript are requested. Clinical and research observations, no matter how brief, similar to those in *The Lancet* (London), are particularly encouraged.

States reporting isolation of the Asian strain are California, Hawaii, Iowa, Michigan, Pennsylvania, Texas, Washington and the District of Columbia. In addition, reports of influenza-like disease outbreaks have been received from Kentucky, Mississippi, Nevada, Ohio, Tennessee, Utah, and West Virginia.

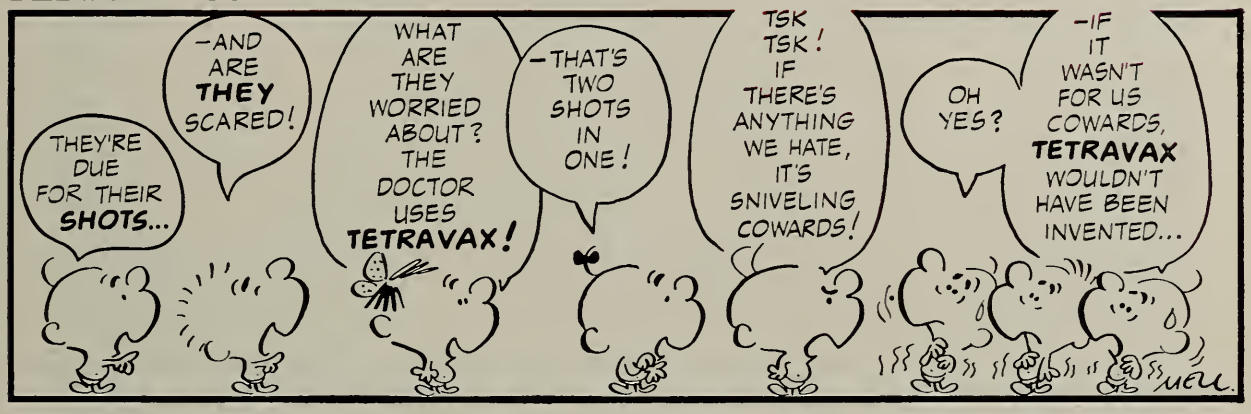
Upwards of 500,000 cases have been reported in Los Angeles where the absenteeism rate from school and work is estimated at about 15 per cent. Eight isolations have been made of the Asian strain. All hospital beds in Fresno were reported filled last week and isolation of the Asian strain has been made there. Merced County has reported about 4,000 cases, with a school and work absentee rate of 15 per cent. Outbreaks also have occurred in Santa Barbara, Sacramento and Tulare County.

Outbreaks are appearing throughout Texas, with current concentrations in San Antonio, Corpus Christi, Austin, Brownsville and Houston. The Brownsville schools report that thirty-five per cent of the student body has been absent.

Nearly 30 per cent of the school and industrial population of Detroit was on the absentee list early this week. Outbreaks also are reported in the Michigan cities of Ann Arbor, Flint and Saginaw.

The largest outbreak in Pennsylvania is centered in Pittsburgh.

The Surgeon General forecast outbreaks in more areas of the country during the next several weeks. Many of these, he said, will probably start in concentrated populations such as schools and factories and spread to communities. Characteristics of the outbreaks thus far do not indicate that an epidemic of the 1957 proportions will occur this year. A large number of individuals, however, can be expected to contract influenza before the season is over. For the majority of individuals, the disease will be quite uncomfortable with fever and generalized aching, but with improvement within a week. For a small proportion of persons, the symptoms may become more severe and not improve rapidly. For these individuals it is especially important that a physician be consulted to be certain that no complications develop.



Reports of deaths from influenza and pneumonia have shown an increase above normal in the past two weeks particularly in Los Angeles, San Antonio, Detroit and Pittsburgh.

The Surgeon General repeated his advice of October 29 that vaccination against influenza is especially desirable for persons in whom the disease would be an added health risk such as individuals with heart or lung disease, pregnant women, and persons over fifty-five years of age with any form of chronic disease. He pointed out, however, that since it takes three weeks following vaccination to develop protection against the disease, it may be too late in many areas to expect vaccination to have a beneficial effect.

In Memoriam

WALTER BAER

Dr. Walter Baer, a Saint Paul physician, died January 16, 1960, of a heart attack. He was sixty-one years of age at the time of his death.

A victim of persecution by both the German Nazis and the Chinese Communists, Doctor Baer began his practice in Saint Paul nine years ago.

Born in Germany, he graduated in 1921 from the University of Dusseldorf Medical School. He became an instructor at the University Medical School following graduation. He fled his homeland in 1940 under pressure and practiced medicine for ten years in Shanghai. In 1950, he was again forced to leave, this time under the pressure from the Communists.

After studying eight months in New York for a license, he became an intern at Miller Hospital in Saint Paul at the age of fifty-two and began practice after completion of his certificate to practice in the State of Minnesota.

Doctor Baer was a member of the Ramsey County Medical Society, the Minnesota State Medical Association and the American Medical Association.

He is survived by his wife, Ilse; a daughter, Margaret, and a sister, Mrs. Annie Hearst, London, England.

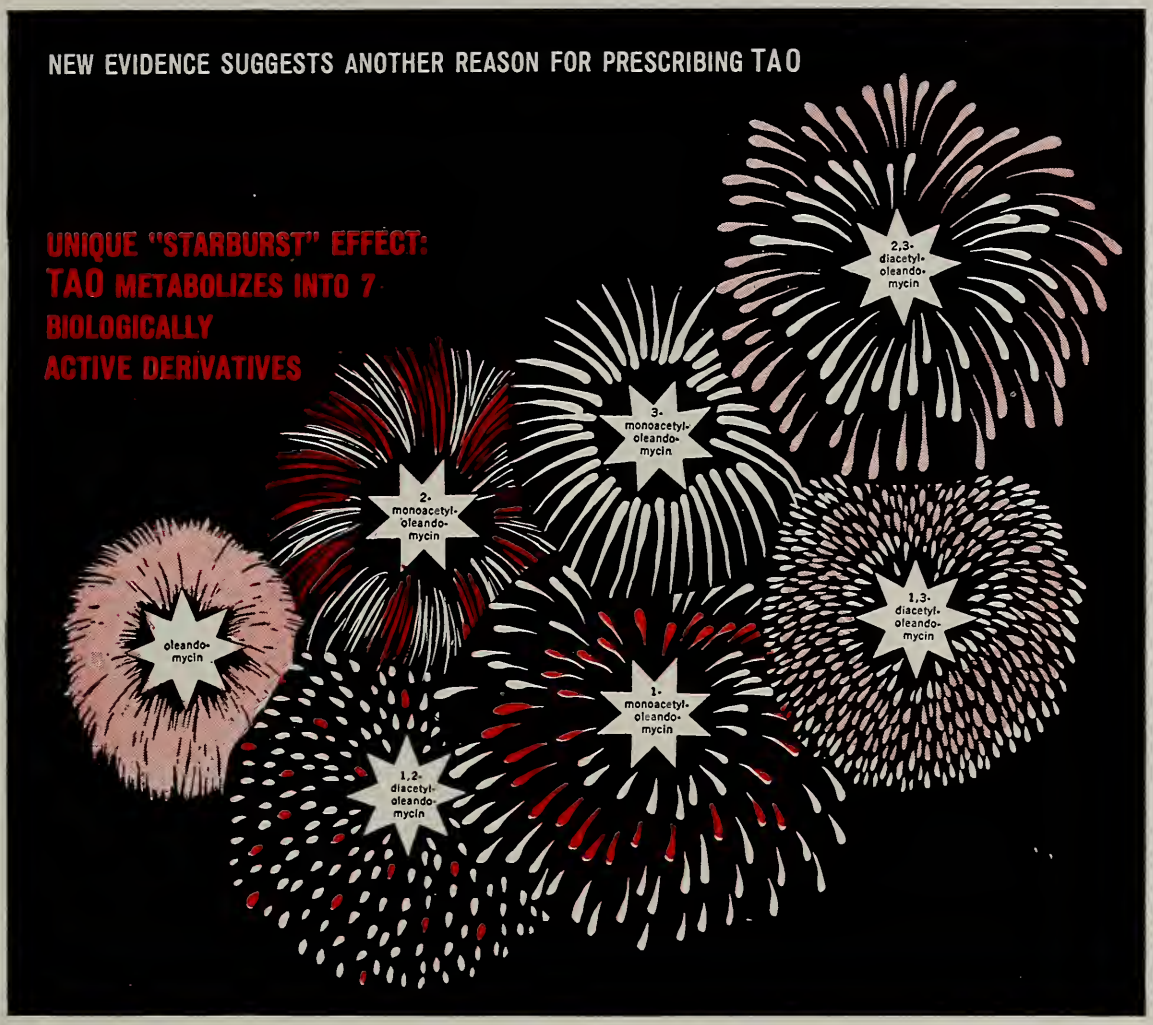
RALPH E. BILLINGS

Dr. Ralph E. Billings, a physician in Franklin, Minnesota, for more than thirty years, died December 19, 1959. He was sixty-nine years of age at the time of his death.

The deceased was born in Jasper, South Dakota, and was graduated from the University of Minnesota Medical School. He was a World War I veteran and was a former Chairman of the Franklin School Board, Past President of the Renville-Redwood County Medical Society, a member of the Minnesota State Medical Association and the American Medical Association.

In addition, Doctor Billings was a member of the American Legion and Saint Luke's Lutheran Church in Franklin.

Survivors include his wife; three daughters, Janet, Mrs. George (Marsha) Noulies of New Orleans, and Mrs. Ronald (Doris) Van Victor of Los Angeles; six sisters and one brother.



LAURENCE H. CADY

Dr. Laurence H. Cady, Minneapolis physician, died December 18, 1959. He was sixty-eight years of age at the time of his death.

The deceased was a member of the Hennepin County

(Continued on Page A-78)

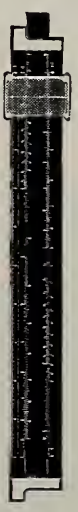
The impression that TAO is an unusually active antibiotic has steadily gained recognition by impressive clinical performance. Now come reports of **in vivo** and **in vitro** biological and biochemical evaluations that show TAO to be indeed unique.[1,2]

TAO differs from other antibiotics in that it is metabolized to multiple active compounds which **remain** active throughout their presence in the body. These 7 derivatives (in addition to TAO) show activity against common Gram-positive pathogens, including resistant strains of **Staph. aureus.**

In light of these findings, take another look at TAO performance: • 92% success in published cases of Gram-positive respiratory, skin, soft tissue and genitourinary infection • Effective against 78% of 64 "antibiotic-resistant" epidemic staphylococci. (In the same study, chloramphenicol was active against 52%; erythromycin against only 25%)[3] • No side effects in 94%; infrequent reactions mild and easily reversed • Quickly absorbed • Highly palatable.

Sound reasons to: Start with TAO to end 9 out of 10 common Gram-positive infections.

Supplied: TAO Capsules—250 mg., and 125 mg., bottles of 60. **TAO for Oral Suspension**—125 mg. per tsp. (5 cc.) when reconstituted; unusually palatable cherry flavor; 60 cc. bottle. Prescription only.



Other TAO forms available: TAO Pediatric Drops: flavorful, easy to administer. **TAO®-AC:** TAO analgesic, antihistaminic compound. **TAOMID®:** TAO with triple sulfas. **Intramuscular or Intravenous:** in clinical emergencies. Prescription only.

LAURENCE H. CADY

(Continued from Page A-76)

Medical Society, the Minnesota State Medical Association and the American Medical Association.

In addition, he was a member of the Saint Anthony Commercial Club and a Past Master of University Masonic Lodge 316.

Doctor Cady was on the staff of Saint Andrew's Hospital in Minneapolis.

The deceased was born in Minneapolis and received his preliminary education at Minneapolis East High School and the University of Minnesota. His medical education was obtained at the University of Minnesota Medical School.

Survivors include his wife, Esther, and three sons, Patrick, Timothy and Michael.

PAUL J. PRESTON

Dr. Paul J. Preston, former Chief of Staff at Asbury Hospital in Minneapolis, died December 29, 1959, at the age of seventy years.

The deceased was a graduate of the University of Minnesota and the University of Chicago Medical School. He was also on the staff of the new Methodist Hospital in St. Louis Park.

For twenty years, Doctor Preston had served as team physician for the Minneapolis Millers. In April of 1959, he was presented with a lifetime American Association pass by the League President.

He was a member of Hobart Methodist Church, Masons and Shriners, the American Legion and Disabled American Veterans. Doctor Preston was Past Commander of the Fifth District American Legion.

The deceased was an Associate Member of the Minnesota State Medical Association, the Hennepin County Medical Society and the American Medical Association.

Survivors include his wife, Marie; a son, James R., and a daughter, Mrs. David Hatlestad, all of Minneapolis and a sister, Mrs. E. O. Sandbo, Stanford, Montana.

RUSSELL M. WILDER

Dr. Russell M. Wilder, emeritus member of the Mayo Clinic staff and world-famed expert on diabetes and medical nutrition, died December 16, 1959. He was seventy-four years of age at the time of his death.

The deceased was born in Cincinnati, Ohio, and received his preliminary education at South Side Academy in Chicago, Illinois. His medical education was received at Rush Medical College located in Chicago, Illinois.

In 1914, Doctor Wilder studied in Vienna for eight months, principally at the First Medical Clinic.

He had been commissioned a First Lieutenant in the Medical Reserve Corps of the Army in 1914. On June 12, 1917, he was ordered to active service at Fort Benjamin, Harrison, Indiana. He went to France in

January, 1918, as a Captain, and Chief of the Medical Service of Evacuation Hospital Number Two. He later served on the headquarter's staff as Chief of War-gas Defense (medical) of the Second Field Army. He left the Army on June 4, 1919.

Doctor Wilder entered the Mayo Clinic, October 1, 1919, as an Associate in the Division of Medicine and Assistant Professor of Medicine in the Mayo Foundation.

On May 15, 1929, Doctor Wilder left Rochester to become Professor of Medicine and Chairman of the Department of Medicine in the University of Chicago. He worked there on osteitis fibrosis cystica and on obesity, Addison's disease and epilepsy.

He returned to the Clinic October 1, 1931, and became Professor and Head of the Department of Medicine at the Mayo Foundation. In this same year, he was appointed a member of the Council on Foods and Nutrition of the American Medical Association.

He became a Senior Consultant in the Division of Medicine of the Mayo Clinic on July 1, 1946. He retired from the Mayo Clinic and Mayo Foundation on December 31, 1950, and became Director of the National Institute of Arthritis and Metabolic Diseases, U. S. Public Health Service, at Bethesda, Maryland, in January 1951. He relinquished the post because of ill health and returned to Rochester in July 1953.

He was President of the American Diabetes Association in 1946-47, and was elected President of the National Vitamin Foundation in 1956. He was a Fellow of the American Medical Association and of the American College of Physicians, and a member of the Association of American Physicians, the American Society for Clinical Investigation, the American Physiological Society, the American Society for Experimental Pathology, the American Institute of Nutrition, the Central Society for Clinical Research, the Central Interurban Clinical Club, the Minnesota Society of Internal Medicine, the Institute of Medicine of Chicago, the Academies of Medicine of Minnesota and Washington, D. C., the Alumni Association of the Mayo Foundation, Society of the Sigma Xi, Alpha Omega Alpha, Nu Sigma Nu and Delta Kappa Epsilon.

Doctor Wilder was made a Master of the American College of Physicians in 1957; The American Diabetes Association conferred the Banting Medal upon him in 1947, and the University of Chicago gave him the Distinguished Service Medal in 1941 and the Howard Taylor Ricketts award in 1949. The Medical Alumni Association of the University of Chicago presented him with the honorary gold key in 1955. The American Medical Association honored him with the Joseph Goldberger award in 1954 and in 1956 the American Bakers' Association gave him an award in recognition of activities in promoting enrichment with vitamins of white flour and bread.

Survivors include his wife; two sons, Dr. Russell M. Wilder, Jr., Topeka, Kansas, and Dr. Thomas C. Wilder, Spokane, Washington.

Doctor Wilder was an Associate Member of the Minnesota State Medical Association, the Zumbro Valley Medical Society and the American Medical Association.

Ulvical Meets Her Need for a Complete Prenatal Supplement

Today's children need attention, guidance and love. That next baby needs attention too; nutrition which meets all of his demands so that he will arrive healthy and happy.

An active mother provided with maximum iron, calcium and vitamins during her prenatal waiting will be healthy and happy too. Ulvical provides her with a maximum amount of iron, absorbable calcium and vitamins in one small sugar coated tablet. Recommend Ulvical . . . you'll know they're *both* healthy.

More easily tolerated . . .

TETANY OVERCOME . . . . . usually within 24 hours

OPTIMAL HEMOGLOBIN LEVELS . . . . in spite of sub-acidity

ULVICAL, THE PREFERRED PRENATAL SUPPLEMENT IS NOW EVEN BETTER!

Each white sugar coated tablet contains:

Calcium Pyrophosphate (Ca 150 mg., P 120 mg.)	7.5 gr.
Ferrous Sulfate, U.S.P. (Fe 38 mg.)	3 gr.
Vitamin A	1,500 USP units
Vitamin D, Natural (Irradiated Ergosterol)	200 USP units
Thiamine Mononitrate (B_1)	1 mg.
Riboflavin (B_2)	2 mg.
Ascorbic Acid (C)	16.66 mg.
Alpha Tocopherol (E)	2 mg.

The Physician's Diary

Tracy physician, **Dr. W. G. Workman**, gave an impromptu address at a recent Kiwanis Club, when he spoke on the important work of the public health service. He pointed out how the government's health department is like a watchdog to safeguard the public from uses of food, medicines and numerous products until proven safe.

* * *

It was learned recently that **Dr. Albert J. Lenarz**, Browerville, has moved to St. Cloud, Minnesota. Doctor Lenarz will be associated with **Dr. J. B. Gaida** in the practice of medicine.

* * *

Dr. John S. Lundy, former member and emeritus founder and head of the Section of Anesthesiology of the Mayo Clinic, has been appointed Associate Professor of Surgery in the Northwestern University Medical School in Chicago. The appointment will be effective until October 31, 1964.

* * *

The Immanuel Hospital medical staff of Mankato at its recent annual meeting elected as President of staff **Dr. F. D. Roth**, who will serve through 1960. Other officers elected were: **Dr. J. C. Wohlrabe**, Mankato, Vice President, and **Dr. H. J. Smith**, Lake Crystal, Secretary. Elected to the Executive Committee were **Dr. D. B. Swenson** and **Dr. J. C. Von Drasek.**

* * *

Dr. Frances E. Schaar, Minneapolis, recently attended the annual meeting of the American Society of Hematology held in St. Louis, Missouri.

* * *

Dr. A. G. Athens, Duluth, a member of the St. Louis County Medical Society since 1922, recently retired from practice.

* * *

At a recent staff meeting of the Divine Infant Hospital in Wakefield, Michigan, **Drs. E. E. Barrett, Wm. B. Martin** and **J. F. Schmid**, Duluth, presented papers on rheumatic fever, differential diagnosis of chest pain and common dermatoses, respectively.

* * *

A member of the Grand Rapids Clinic, **Dr. Calvin J. Johnson**, has been inducted as a new Fellow in the American College of Surgeons.

* * *

The first medical research grant in the history of the Minnesota Medical Foundation was awarded recently. The grant, for $13,716, went to **Dr. Frederick C. Goetz**, of the Department of Medicine, University of Minnesota Medical School, to finance a two-year research project aimed at developing substitutes for insulin in the treatment of diabetes. A team of scientists and technicians will participate.

* * *

Dr. H. J. Svien, Mayo Clinic neurosurgeon, has been appointed North American Vice President of the Section of Neurosurgery of the Pan American Medical Association.

* * *

Dr. Charles P. Floyd has recently joined the staff of Willmar State Hospital. Doctor Floyd is a graduate of the University of Michigan School of Medicine, and interned at St. Joseph's Hospital in Denver, Colorado. He is a native of Estancia, New Mexico.

* * *

A Mayo Clinic staff member, **Dr. Robert R. Kierland**, has been re-elected Secretary-Treasurer of the American Academy of Dermatology and Syphilology.

* * *

Dr. Maynard Cohen, University of Minnesota neurologist, has been awarded a grant of $14,171 by the National Multiple Sclerosis Society, it was announced recently. The grant was made for one year's research into multiple sclerosis.

* * *

The American Academy of Dermatology and Syphilology recently elected **Dr. Francis W. Lynch**, St. Paul, as President at the group's eighteenth annual meeting in Chicago. Doctor Lynch succeeds Dr. Anthony C. Cipollaro, Professor and Director of the Department of Dermatology and Syphilology at the New York Poly-Clinic Medical School and Hospital in New York City.

* * *

Waseca, Minnesota, has a new physician. **Dr. Thomas Rohrer**, a native of Waterville, has begun general practice in the First National Bank Building. Doctor Rohrer is a graduate of the Waterville High School and of the University of Minnesota Medical School. He served his internship in Sacramento, California.

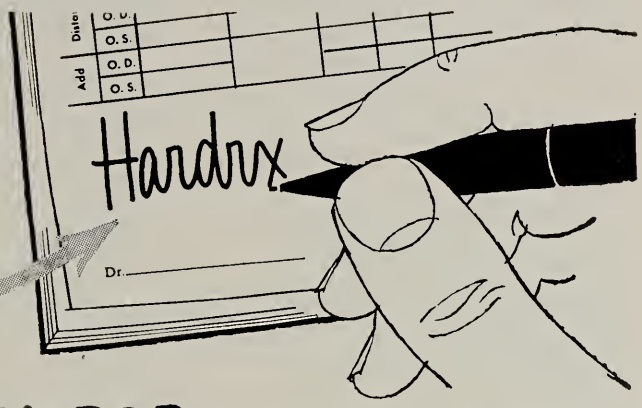
* * *

Dr. R. T. Healy, Pierz, was recently honored at a surprise dinner party in honor of his fifty years of medical practice.

* * *

A Mayo Clinic staff member, **Dr. J. Arnold Bargen**, has been appointed a member of the Executive Committee of the Mississippi Valley Medical Society, according to Dr. Harold Swanberg, Quincy, Illinois, Secretary-Treasurer of the organization. Doctor Bargen previously had been elected to the Board of Directors of the Society.

* * *



The Fridley Jaycees recently presented a plaque to **Dr. Alan R. Jay**, in recognition of his donation in time and effort to the anti-polio vaccination program. The award was made at a dinner meeting of the Jaycees.

* * *

Six Marshall physicians have just completed moves from rented offices into their own medical buildings. One building, the Marshall Medical Centre, is occupied by **Drs. J. E. Murphy, P. C. Hedenstrom** and **R. W.**

make protection a part of every prescription

BENSON'S HARDRx SAFETY LENSES!

Eyes worth correcting are worth protecting. All of your patients *deserve* maximum safety from dangerous and costly lens breakage. Benson's HARDRx safety lenses — ground to a formula-determined thickness and scientifically heat-treated — are toughened to resist impact.

To impress on your patients that you've prescribed the ultimate in lenses for them, the identifying tag shown at left is attached to each pair of genuine HARDRx lenses. Your patients will appreciate your thoughtfulness in prescribing this extra protection . . . and will tell their friends of your quality service.

Join the growing number of doctors who specify HARDRx regularly. Remember: HARDRx prescriptions receive the same prompt handling.

GENERAL INFORMATION

Authors

Manuscripts should be addressed to Arthur H. Wells, M.D., Editor, 915 East First Street, Duluth 5, Minnesota. Telephone RA 7-6636 or JA 5-2319. Original papers prepared for publication solely in Minnesota Medicine will be considered by the Board of Editors providing they fulfill the following editorial standards. Manuscripts should be typed double spaced on white paper with at least 1-inch margins. The original (not a carbon copy) is requested. The title on the first page should be under six words if possible or divided into two parts. The author should give his highest degree, his institutional position or his relationship to a hospital or medical organization which he may be addressing. Pages should be numbered consecutively and the author's last name should appear at the top of each page.

Bibliographical references should appear on a separate sheet entitled References. They should appear and be numbered consecutively in the order in which they first occur in the text (not alphabetically). Citations in the text require reference numbers if the author's or authors' names are not used or if there is more than one reference to the same author or group of authors. All references to author should appear in the list of References and no references should be included which are not in the text. The style and exact punctuation used in the J.A.M.A. references are requested. Journal references should include: *Author's last name, initial., initial.: title of paper. Abbreviated name of journal, volume number: page, year.* Book references should give author, title, edition number, city, publisher and year.

Illustrations (photographs, tables and graphs) should be submitted separately and not combined in the text. There should be a separate sheet entitled "Illustrations" which contains the various types of illustrations listed separately and numbered in the order in which they appear in the text. All photographs must be in black and white, clear cut, contrasting, and on glossy stock. Instructions for combining photographs are acceptable. Any number of illustrations over 4 are charged to the author. Combinations of photographs up to one-half page (6 x 4⅜ inches) count as 1 illustration.

Animal Diseases Transmissible to Man

Pathogenic microorganisms, in their struggle for survival, adapt to new hosts and changing circumstances. New human-animal disease relationships are being reported with increasing frequency. Here the author discusses the most prevalent zoonoses, the term being applied to infectious diseases which are common to human beings and animals.

ROBERT J. ANDERSON, M.D., M.P.H.
Atlanta, Georgia

Presented at the Annual Meeting of the Minnesota State Medical Association, Duluth, Minn., May 27, 1959.

Dr. Anderson is Assistant Surgeon General, Chief, Communicable Disease Center, Bureau of State Services, Public Health Service, U. S. Department of Health, Education, and Welfare, Atlanta, Georgia.

THE CONNECTION between human and animal health is acquiring greater significance today as new disease entities are found to afflict both man and animals and as previously unsuspected disease relationships become manifest. More than 100 infectious diseases which are common to humans and animals have been listed by the 1959 WHO Expert Committee on Zoonoses—a substantial increase over a few years ago. The importance of these interrelationships is further demonstrated by the increasing frequency with which the phrase "in man and animals" appears in the titles of medical and research papers dealing with a wide variety of diseases.

Recently discovered pathogenic microorganisms, especially viruses, account for many of the newly described disease entities. In 1948, two-thirds of the sixty viruses known to infect man had other animals as primary hosts. Although they involved man secondarily, they often affected him more

severely than they did other species. More recently, some seventy new so-called "human" viruses have been established and studied, including a number of respiratory viruses and enteroviruses of the Coxsackie and ECHO groups. Originally, these viruses were thought to be specific for man, but as experience with them has broadened, a correlation with animals has been found for many of them.

For example, Para influenza 3 virus, which causes a significant amount of upper respiratory illness and pneumonia in children, has been isolated from cattle in association with outbreaks of shipping fever. In Maryland and Pennsylvania, fourteen separate strains of this virus have been recovered from calves, many of which had respiratory disease. In order to determine the human significance of extensive bovine infections with Para influenza 3 virus, we must learn more about the infection and disease in cattle. Looking toward prevention, the National Institute of Allergy and Infectious Disease, in collaboration with the University of Maryland and commercial companies, is investigating the possibility of a vaccine for humans and calves.

Sendai, a new myxovirus isolated in Japan, is sometimes referred to as Influenza D. An important cause of pneumonitis in infants, it has also been recovered in swine and rodents. As a final example, the notorious salivary gland virus family has been found to have related, but species-specific, representatives in mammals other than man.

There is probably no simple answer as to why new human-animal disease relationships are being reported with increasing frequency. Pathogenic microorganisms, in their struggle for survival, adapt to new hosts and changing circumstances. We are becoming more aware of human-animal disease relationships as new and improved diagnostic techniques permit us to identify and associate previously unsuspected animal-disease agents with clinical syndromes in humans. For example, the virus responsible for Newcastle disease, which is a problem in the poultry industry, produces conjunctivitis and systemic effects, including chills, fever, and influenza-like symptoms, in man.

The interactions of host, parasite, and environment are subject to rapid change, as expanding human populations with their billions of domestic animals pre-empt more and more of the earth's surface and introduce great numbers of susceptible hosts to unfamiliar disease agents. Some diseases which were once primarily identified with wildlife have become established in livestock and in pet animals, and through closer contact have become a greater threat to man. Leptospirosis is an excellent example of this. Until twenty years ago, leptospirosis in man (Weil's disease) was identified only with rats. Then Meyer and his colleagues reported that Canicola fever, a new form, was transmitted from dogs. Now the disease is known to affect many kinds of wild and domestic animals, including birds, and it is being diagnosed increasingly often in man.

Some of the more important communicable diseases of man and animals have been controlled to a degree in the United States and in the advanced western nations. In this country, certain animal diseases that affect both the nation's health and its livestock economy have been made the special target of co-operative programs carried out by public health and veterinary regulatory agencies. As a result of these concerted control efforts, bovine tuberculosis is rarely a source of human disease, and the incidence of brucellosis is declining.

Today I would like to discuss a few of the most important diseases that could be eliminated as health hazards to man if we could wipe them out at their animal sources.

None inspires greater dread than rabies; yet, from the standpoint of its incidence in man, this has become a comparatively rare disease, claiming six human lives last year. In the past decade, the number of reported cases in dogs—the chief source of human infection—has been reduced by 75 per cent as a result of extensively applied control measures. Nevertheless, rabies is still of grave concern to the estimated 2½ million individuals who are bitten or scratched by animals each year and to the medical practitioners who must determine how to treat them. It is estimated that approximately 30,000 to 40,000 of these persons are bitten by rabid or suspected rabid animals and must undergo the course of treatment, which is often painful and sometimes hazardous.

Although there has not been a case of human rabies in Minnesota since 1917, last year more than 2,000 persons in Minneapolis and St. Paul and nearly 1,500 persons in other parts of the State were bitten or otherwise exposed by animals. As usual, children were the chief victims. At least 232 of the exposed persons received antirabies vaccination treatment.

There is little excuse for a rabies problem in any

urban community today when it has been shown that rigidly enforced canine immunization laws, control of stray dogs, and public education can eradicate it. The sylvatic reservoir presents a far more difficult problem in control. While the incidence of rabies in dogs has been declining, the number of cases reported in wildlife and livestock species has multiplied.

I understand that Minnesota experienced a record number of animal rabies cases last year, with skunks accounting for more than half of them. Because wildlife rabies, especially in skunks, is increasing in the Midwest, CDC (Communicable Disease Center) recently established a rabies investigation station at Poynette, Wisconsin. Our people are co-operating with the State Department of Health, Livestock Sanitary Board, and Department of Conservation in carrying out an investigative program on your rabies problem.

Since the development of hyperimmune antirabies serum and new types of immunizing agents, treatment for humans has advanced. Hyperimmune serum, administered as soon as possible after exposure, protects the victim during the interval required for antirabies vaccine to take effect.

The possibility of immunizing humans against rabies before exposure has been under investigation for several years. New vaccines produced by passing virus through chick embryos have now been administered experimentally in many parts of the country. Preliminary results, as measured by the antibody response in vaccinated individuals, are encouraging. If these vaccines prove satisfactory, they will be a boon to individuals who run a certain risk of exposure to rabies, for example, veterinarians, dog wardens, postal and delivery men, and laboratory workers.

Q fever is a widespread rickettsial infection of animals that rarely causes recognizable disease in its animal hosts but may produce a variety of symptoms in man. The causative organism, *Coxiella burneti,* is most frequently found in cattle, sheep, and goats, but a number of small mammals, including rodents, and wild and domestic birds have also been described as carriers.

Transmission of Q fever to man usually occurs by direct contact with an infected animal or its environment. In naturally infected livestock, a rickettsial aerosol is liberated during parturition, contaminating the surrounding area. The organism is often found in the milk of infected cattle, but it can be destroyed if the pasteurization temperature is raised one or two degrees above that generally used.

When it is diagnosed in man, Q fever usually manifests itself as an influenza-like syndrome characterized by sudden onset, headache, malaise, and thoracic pain. X-rays of the lungs reveal a patchy infiltration which frequently clears up in a few days. In elderly people, the disease may be generalized and terminate fatally. In many instances, Q fever can be diagnosed only by serological test. As for treatment, the disease in man responds well to the broad spectrum antibiotics.

Control of Q fever is difficult. Vaccination of certain high risk occupational groups, immunization of cattle, and the proper pasteurization of milk and milk products are all considered to be of some value.

The psittacosis-ornithosis reservoir is no longer confined to pet birds; the disease is prevalent in many avian species in this country, especially in domestic poultry. During the past few years, epidemics of human disease became increasingly common among workers on poultry farms and in poultry processing plants from coast to coast. In 1954, a large reservoir of the disease was uncovered in western Wisconsin and eastern Minnesota. At that time, infections were largely subclinical, but were occasionally manifested by transitory respiratory symptoms. The turkey prototype showed low mammalian virulence in the laboratory. Last year, Dr. Rex Graber of the Chippewa Falls, Wisconsin, Health District, and Dr. Benjamin Pomeroy, Professor of Veterinary Bacteriology and Public Health, University of Minnesota, published an epidemiological study of a human outbreak transmitted from turkeys in Wisconsin. The authors believe that the ten human cases they describe are the first to demonstrate that turkey ornithosis strains of low virulence are capable of causing disease in man. Most of the victims were employed in the killing department of a processing plant and were infected through airborne transmission of virus in dust particles and spray aerosols.

As an interesting side note Dr. Pomeroy himself did not get psittacosis until this year, even though he had worked with this highly infectious disease for more than a decade.

The preventive approach to this disease has been through antibiotic regimes incorporated in the daily diet of psittacine birds and poultry.

Brucellosis is a major problem in many parts of the world, but its importance in this country is

diminishing as a result of the bovine control program. As recently as 1947, it was estimated that 20 to 30 per cent of the cattle in this country and 5 to 10 per cent of the swine were infected, and human cases were being diagnosed at a rate of about 10,000 per year. In 1958, as a result of the national campaign, fewer than 800 human cases were reported, mostly among veterinarians, farmers, and workers handling animals and animal products. The incidence among dairy and range cattle has also dropped precipitously. By the end of 1958, sixteen states had been accredited by the national brucellosis control program, which means that less than one per cent of their cattle show a positive serum agglutination. Minnesota is one of these states.

Brucellosis in man responds to the broad spectrum antibiotics, but relapses frequently occur and some individuals develop hypersensitivity to the *Brucella* organisms which persists beyond the acute clinical state.

Another bacterial disease — leptospirosis — is emerging as an important problem. One of the most widespread diseases in nature, it has been found in all kinds of animals, domestic and wild, and even in birds. In man, it is usually an occupational disease but it may be a recreational accident. Infection in man occurs through direct contact with diseased animals or indirectly through contact with water or soil contaminated by the urine of infected animals. The leptospires enter the body usually through the externally accessible mucous membranes or abrasions of the skin.

Symptoms of leptospirosis in man vary. Although they are frequently severe, the mortality rate is low. The disease is manifested by fever, headache, myalgia, and meningitic signs. Jaundice is seldom seen except in severe cases. Recently CDC developed a multiple antigen for serological screening tests, which is now being evaluated in health departments, hospital laboratories, and veterinary diagnostic centers.

Tetracyclines in large doses initiated within three days of onset of the disease in man is relatively effective as a therapeutic procedure, but it has no value if its use is delayed as much as four days.

Control of leptospirosis in animals is most difficult because of the wide range of the organism and its survival in water and soil. Vaccines for man and animals offer the best solution; they are now being developed and field tested.

It would be difficult to overestimate the incidence of enteric disease in man and animals. We know far more about the bacterial agents responsible for gastroenteritis and diarrheal disease than we do about the viral causes, which may be equally important. Among the enteric bacteria common to animals and man, the genus *Salmonella* has universal distribution. It has over 500 antigenic serotypes, all pathogenic for man, animals, or both. Their natural habitat is in the intestinal tract of animals, but organisms have been isolated from a wide variety of situations. Many human outbreaks of salmonellosis have been traced to contaminated eggs, milk, poultry, and meat, just as others have been traced to human carriers.

The ubiquitous nature of the organisms poses many problems. Our most effective means of control is to instigate measures of good sanitation and personal hygiene in food processing plants and in the home. Control in animals is difficult, since many species may become asymptomatic carriers and act as reservoirs of infection to other animals and man. CDC is serving as the National Salmonella Typing Center. Through precise phage typing, it is now possible to trace outbreaks of salmonellosis to their original source.

Anthrax in animals and among rural human populations has declined greatly in this country, although it is a disease that still requires constant vigilance. Most of the human cases of anthrax in the United States in recent years have occurred in industrial workers handling imported contaminated goat hair, wool, hides, and bones.

Soil is a reservoir of anthrax spores for both animals and man. Four cases of anthrax in children in Arkansas last year, and two additional suspected cases, substantiate this fact. In each instance, the children had contact with soil on their premises where livestock had died of anthrax and had been dragged into the fields to be burned. The children had no direct contact with the animals.

There is a possibility that the use of contaminated wool and hair waste from mills as fertilizer may be responsible for introducing anthrax into a non-endemic rural area. Just a few weeks ago, a New Jersey farmer, living reasonably close to some Philadelphia textile mills, contracted cutaneous anthrax after one of his cows died. Several hogs that were fed the intestine of this cow subsequently developed anthrax.

Fortunately, this disease usually yields to penicillin.

The dermatophytes have many links between man and animals. Investigations at CDC have shown that from 70 to 80 per cent of ringworm cases in rural populations and 10 to 30 per cent of the cases in urban populations are of animal origin. Farmers and their families become infected by handling cattle at milking time or contacting the fungus in the barn. Cattle ringworm is a winter disease, and most of the human infections are also. The disease often clears up spontaneously in the cattle and in the people who tend them when warm weather returns and the animals are put out to pasture. Much of the ringworm seen in children is transmitted to them by their pets and even by stray cats and dogs which they handle. Control of these infections in children, therefore, must be based on the elimination of the animal disease. The most promising development in the control of dermatophytes is the success that is being obtained therapeutically in humans and animals with griseofulvin. This remarkable antibiotic, discovered and evaluated in Great Britain, is administered orally. It has proved effective in the treatment of ringworm of the scalp, onychomycosis, tinea corporis, and tinea pedis.

Now, I would like to tell you a little about the fluorescent antibody technique, our most promising new laboratory diagnostic tool for the rapid identification of microbial agents. This procedure was first discovered more than ten years ago by Dr. A. M. Coons and others at the Harvard University School of Medicine, and has been widely used in experimental studies. During the past four years, CDC has explored the procedure for routine public health laboratory use. It has recently had its first successful test in the field.

This field trial, conducted with the co-operation of the Florida State Board of Health, involved 144 cases of suspected rabies in animals. Specimens suspected of containing rabies virus were tested with the technique within a matter of minutes, also put through the standard two-to-three week mouse inoculation test. The results were 100 per cent in agreement. With this test, the need for specific treatment would be evident immediately and could be started without delay.

A field trial, comparable to those on rabies, is now in progress on the diagnosis of streptococcal (beta hemolytic) infection. Specimens will be tested by the conventional method also, which takes at least three days. With the new technique, the test can be done in minutes although usually about three hours is allowed. Rapid identification of beta hemolytic streptococci would permit adequate therapy to be started early enough to prevent rheumatic fever.

Less advanced, but also at a preliminary testing stage, are efforts to adapt the technique in tests for syphilis, gonorrhea, toxoplasmosis, and several other diseases.

In this procedure, an antibody solution of high titer conjugated with fluorescein is employed as an immunochemical stain. This is applied to smears made from clinical specimens. When conjugated antiserum contacts homologous antigen, the fluorescein-antibody is fixed. The unreacted and indifferent fluorescent proteins are then washed away and the smear is examined microscopically. An ordinary microscope, fitted with appropriate filters and with the field illuminated by intense ultraviolet light, reveals the brilliant yellow-green glow from the fixed fluorescent antibody, thus showing the presence and location of the specific organism.

In addition to its speed and simplicity, the new testing method has the advantage of working when only a few organisms are present. The test can also be used with contaminated specimens. Consequently, the test can often be made directly on the specimen, with no intermediate steps, at a tremendous saving of time, staff, and money.

When testing materials and methods are perfected for the various communicable diseases, and when laboratory technicians are trained to use them, the whole system of laboratory procedures for the identification of infectious agents will be revolutionized by the fluorescent antibody technique.

In addition to such research activities, CDC provides epidemiologic services, laboratory diagnostic services, and training to help State and local health departments develop their own programs for the prevention and control of human-animal diseases. Through these agencies the practicing physician has access to highly specialized resources to aid him in safeguarding his patients and his community against infectious diseases. Because the zoonoses present a vast and difficult problem in this country and throughout the world, the Communicable Disease Center has built an extensive program around them.

Skin Cancer Therapy

Some Dermatological Surgical Aspects

Presented at the Symposium on Skin Cancer for Dermatologists, University of Minnesota, October, 1957.

Skin cancer, the commonest cancer of man, is deserving of more attention not only by the dermatologist, but also by the general practitioner. In this article, basal cell epitheliomas are described most completely because of their frequency. The clinical diagnosis versus the histologic diagnosis is reviewed, and a very good description of the technique of biopsy is presented. The methods of treatment are clearly outlined. The author stresses the fact that the choice of the proper modality requires training and experience.

ALFRED W. KOPF, M.D.
New York, New York

SKIN CANCER is the most common cancer of man[1] and includes all degrees of clinical malignancy from the very common, locally destructive, non-metastasizing basal cell epithelioma to the relatively uncommon, rapidly disseminated, malignant melanoma. The vast majority of skin cancers can be cured by adequate dermatologic surgical, radiation or chemosurgical methods but answers are still wanting to such questions as, "What is the *best* way to treat a particular skin cancer? Which method results in the highest cure rate?" and, "How can the best cosmetic result be achieved?"

In an attempt to answer these questions and others, a clinico-histopathologic study of visible skin tumors, their management, and end results was initiated in 1955 at the New York Skin and Cancer Unit.*

This dermatologic clinic has approximately 75,000 patient visits yearly, of which 12,500 are new patients. Of these new patients, almost one out of twenty presents himself for an oncologic problem.

Figure 1 shows the flow of patients through our institution. New patients registering in the Skin and Cancer Unit are sent to the Oncology Section for diagnosis and recording of the many facts which are considered important for future evaluation. The patients are then referred to the various treatment sections for specialistic dermatologic therapy which, for the most part, is carried out either by the attending dermatologists or by physicians taking post-graduate dermatological training under the supervision of the attending staff.

Upon completion of treatment, the patients re-

From the Department of Dermatology and Syphilology of the New York University Post-Graduate Medical School (Dr. Marion B. Sulzberger, Chairman) and the Skin and Cancer Unit, University Hospital, New York University-Bellevue Medical Center.

turn to the Oncology Section for continued follow-up. The bulk of the information collected is recorded and coded in such a manner that it later can be transferred to punch cards.† The main categories included on the punch cards are indicated on Figures 2 and 3.

In order to afford complete care of the cancer patient, there should be a common meeting ground for members of the various medical specialties who are intimately concerned with the therapy of skin cancer. This need has been met by a Tumor Conference which meets weekly to examine and discuss the problem cases of neoplasms of the skin and of the visible mucous membranes. This conference is attended by dermatologists, surgeons, radiologists and pathologists, as well as undergraduate, graduate and post-graduate students and staff physicians. This conference provides an opportunity for exchange of thought regarding the various specialty approaches to a given problem, offers the patient a type of consultation often beyond reach of the average clinic patient, and provides excellent teaching sessions for the student and practitioner. In addition, the opinions and recommendations of the members of the Tumor conference are also available to staff members for their private patients.

Basal Cell Epitheliomas of the Face

Skin cancer includes a wide variety of malignant neoplasms including epitheliomas, malignant melanoma, sarcomas, et cetera. In this brief presentation, it will not be possible to discuss the surgical therapy of all malignancies of the skin. I will therefore limit the subject to surgical management of the most common type of skin cancer, the basal cell epithelioma, in the location it is most frequently encountered, namely, the face.

To date, over 3,000 patients have registered in the Oncology Section of the Clinic. Of this total, certain information concerning the first 600 consecutive patients (January, 1955 to April, 1956) has been abstracted from the punch cards for this preliminary report.* A total of 740 benign

*It should be stressed that this material represents raw data and has not undergone statistical analysis.

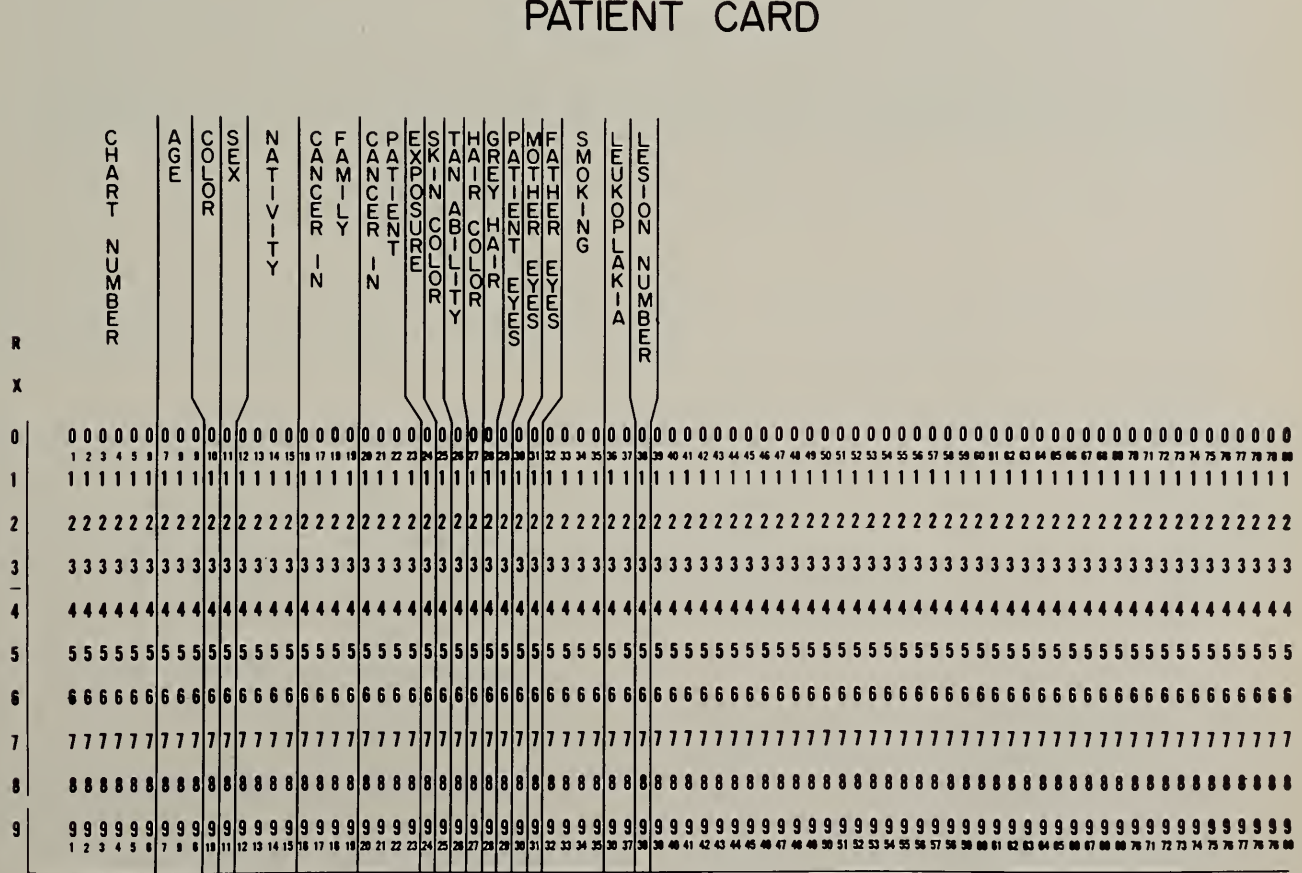

Fig. 2. Punch card illustrating type of information recorded concerning the patient.

and malignant tumors were recorded in these 600 patients, that is, some patients had more than one presenting tumor. Of the 740 lesions, 385 (52 per cent) occurred on the face.

confirmed basal cell epitheliomas was reviewed for certain facts, including:

1. *Age.*—The majority of patients were beyond fifty years of age (Fig. 4).

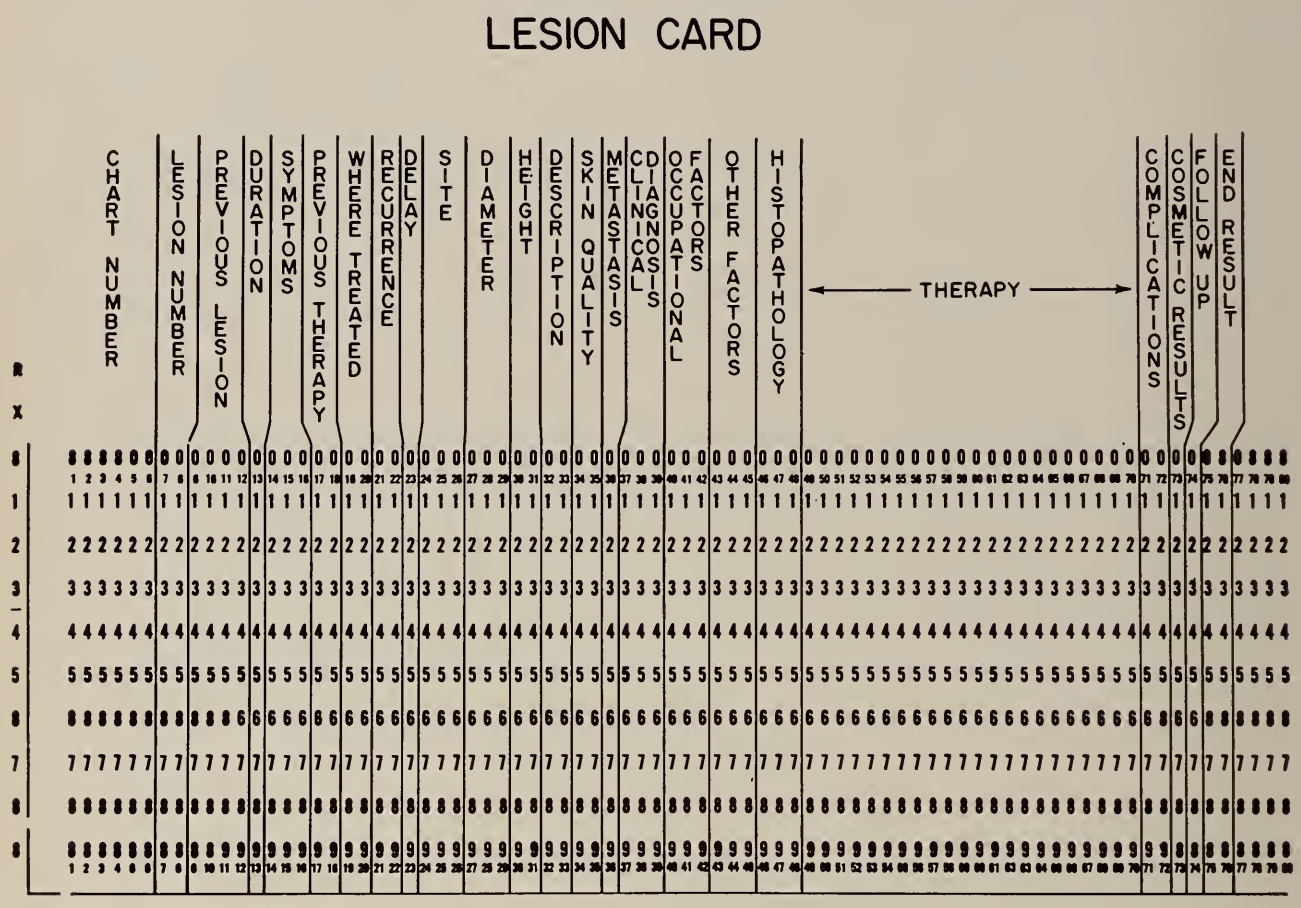

Fig. 3. Punch card illustrating type of information recorded concerning the lesion.

TABLE I. FACE LESION DIAGNOSES

Diagnosis	Diagnosis Based on		
	Histology	Clinical Findings	Total
Basal cell epithelioma	123	33	156 (40%)
Basosquamous carcinoma	2	0	2 (1%)
Squamous carcinoma	16	3	19 (5%)
Malignant melanoma	0	0	0
Precanceroses	30	11	41 (11%)
Seborrheic keratoses	17	14	31 (8%)
Hemangiomas	1	21	22 (6%)
Pigmented nevi	20	35	55 (14%)
Miscellaneous tumors	34	25	59 (15%)
Total	243	142	385(100%)

Basal cell epitheliomas were the most common tumors of the face *for which patients sought medical advice* (156 out of 385). Of the 156 basal cell epitheliomas of the face, 123 were diagnosed histopathologically and the remainder clinically (Table I). The information gathered on these 123

2. *Size.*—Of the lesions 55 per cent were less than 10 mm. in largest diameter, and 96 per cent were less than 20 mm. in largest diameter (Fig. 5).

3. *Color of Patients.*—Whereas 89 per cent of our general clinic population is White, 10 per cent Negro and 1 per cent Yellow, 100 per cent of the basal cell epitheliomas occurred in White patients.

4. *Sex.*—The sex distribution was essential equal (53 per cent men, and 47 per cent women).

5. *Duration.*—Figure 6 illustrates the duration of the presenting lesion prior to the time the patient sought medical advice.

6. *Clinical Diagnosis.*—Of the 123 histologically proven basal cell epitheliomas, 85 per cent were correctly diagnosed clinically by the staff dermatologists. The principal errors occurred in the

differential diagnosis between superficial basal cell epitheliomas and Bowen's disease, and between basal cell epitheliomas and squamous or basosquamous cell carcinomas. In only eight instances to coming to our clinic. It is shocking that the type of "treatment" received by almost one half of those patients previously treated consisted of the application of various ointments.

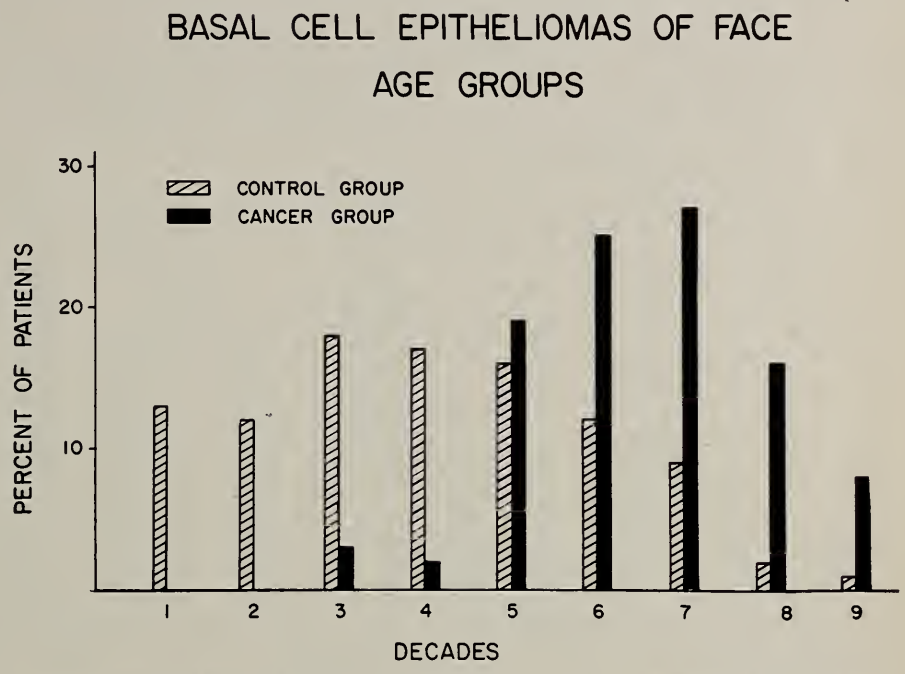

Fig. 4. The "control group" consisted of 252 consecutive patients with various dermatoses chosen from the general clinic population.

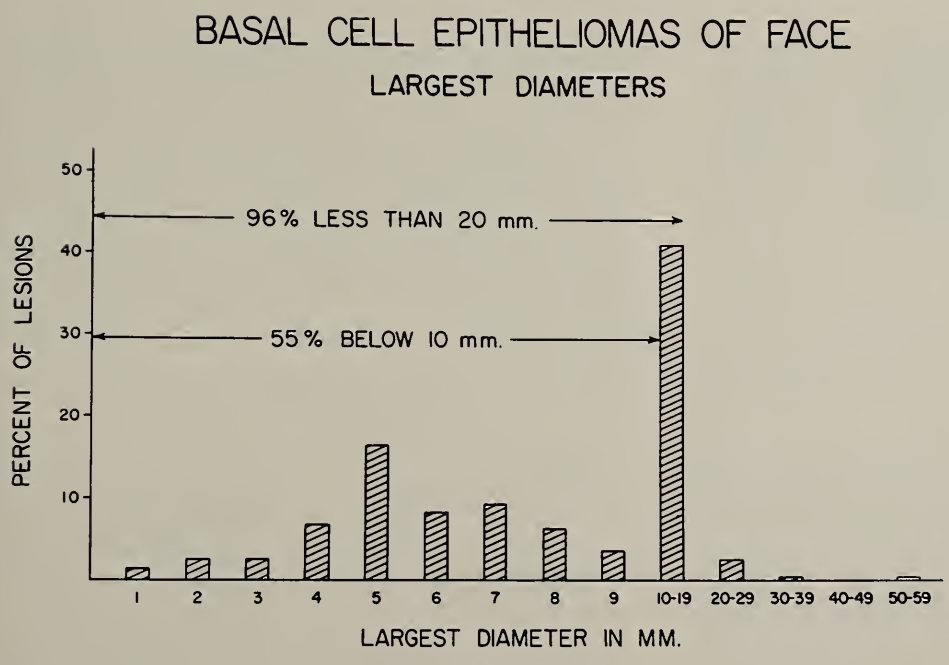

Fig. 5.

were basal cell epitheliomas not clinically diagnosed as malignant tumors but were instead mistaken for benign lesions.

7. *Previous Therapy.*—Of these epitheliomas, 41 per cent received some form of therapy prior

8. *Anatomical Distribution.*—Figure 7 depicts the distribution of the basal cell epitheliomas* on

*Of the total of 740 lesions reviewed in this preliminary study, 175 were histologically proven basal cell epitheliomas. Of these, as stated above, 123 or 72% occurred on the face.

the face showing that the most frequent areas involved are the forehead, cheeks and nose.

9. *Therapy.*—Table II lists the manner in which these 123 basal cell epitheliomas of the face

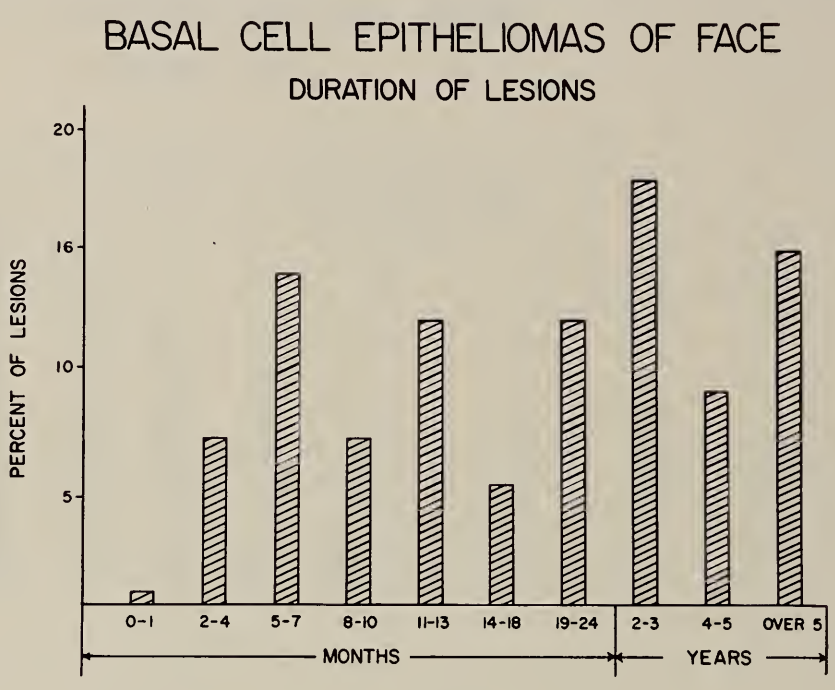

Fig. 6.

TABLE II. TYPES OF THERAPY USED AT THE NEW YORK SKIN AND CANCER UNIT FOR THE TREATMENT OF 123 CONSECUTIVE BASAL CELL EPITHELIOMAS OF THE FACE

Therapy	No. Cases	Per Cent
Electrosurgery	57	46%
Cold steel surgery	37	30%
X-radiation	20	16%
Sherwell method	1	1%
More than one modality	8	7%

were managed in our clinic; 76 per cent were treated by various surgical methods and 16 per cent by radiation.

The prime concern of the dermatologist in the therapy of all basal cell epitheliomas is complete eradiation of the tumor. But because of its common location on the face, an important secondary concern in this management should be to obtain the best cosmetic result possible. With these goals in mind, I would like to pass to a discussion of some of the surgical modalities used by dermatologists for the diagnosis and management of this variety of skin cancer (Table III).

Biopsy

It is extremely important that every skin tumor be subjected to histopathologic examination. This step is essential for the following reasons:

1. Clinical diagnosis always carries with it some chance of error, and, in certain instances the error may result in serious mismanagement. An adequate biopsy specimen examined by a qualified pathologist usually avoids this pitfall.

2. Therapy of some varieties of a given tumor differs according to the histologic type. For example, sclerosing (morphea-like) basal cell epitheliomas are relatively radio-insensitive and are difficult to completely remove by electrodesiccation and curettage because of the dense fibrosis. With few exceptions, then, this type of basal cell epithelioma is usually best treated by surgical excision.

TABLE III. SURGICAL MODALITIES EMPLOYED IN THE MANAGEMENT OF BASAL CELL EPITHELIOMAS OF THE FACE

ELECTROSURGICAL	Electrodesiccation Electrocoagulation Electrocutting Electrocautery
CHEMOSURGICAL	Mohs' technique
COLD STEEL	Scapel Punch Curette
OTHER	Sherwell method

3. The accuracy of statistics of skin cancer incidence, recurrence, radiosensitivity, metastases, et cetera, depends on accurate histopathologic diagnosis. This is vividly exemplified by Becker[2] who

showed that the error in the clinical diagnosis of malignant melanoma approaches 50 per cent. Obviously, any reports of therapeutic results achieved on lesions diagnosed as malignant melanoma on

It is often worthwhile to discuss the technique of performing the biopsy with the pathologist who will be reviewing the sections. The surgeon thus can use the method of labeling specimens pre-

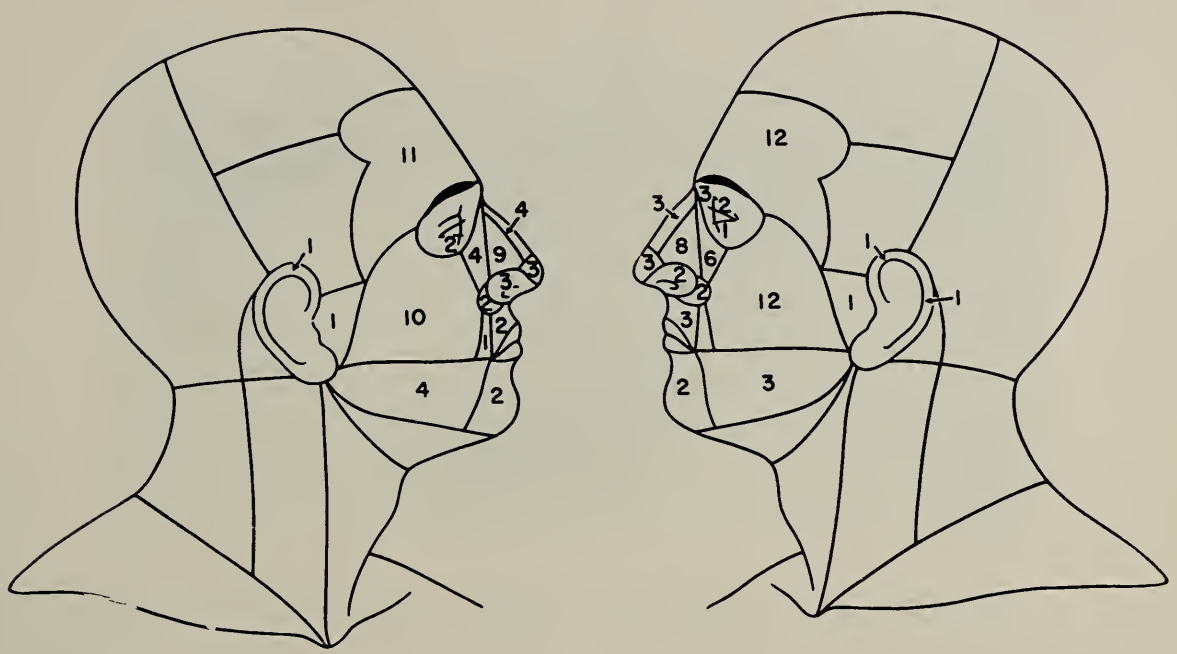

Fig. 7. Anatomical distribution of 123 basal cell epitheliomas of the face.

clinical grounds alone could not be considered valid if the diagnosis was incorrect in half of the patients.

The biopsy may be performed in such a manner that it includes the entire tumor *(excision biopsy)* or only a portion of it *(incision biopsy)*. It is essential that the operative note clearly state which of these procedures was carried out. When the dermatologist is confronted with a relatively large tumor, a tumor in a cosmetically important or relatively inaccessible site, or a tumor which will probably be treated by irradiation, he may justifiably hesitate to remove the entire lesion for histopathologic diagnosis. In such circumstances, a portion of the basal cell epithelioma may be removed with the punch, scalpel, curette, scissors or by the electrocutting current.

What constitutes an adequate biopsy specimen? This depends on the nature and site of the tumor. For example, a 3 millimeter punch biopsy specimen may be entirely adequate for a basal cell epithelioma on the tip of the nase, but would be inadequate for a two centimeter keratoacanthoma at that site. With a few exceptions a well chosen biopsy specimen 0.5 to 1 cm. in diameter will suffice.

Fig. 8. Biopsy technique. Shaded area represents the tumor tissue. Biopsy specimen is bisected by the physician at the time of the operation.

ferred by the pathologist (for example with dyes, incisions or sutures) so that if on microscopic examination tumor tissue is found to extend to the edge of the incision, the precise area can be identified.

What portion of the tumor should be removed for biopsy? The preferred method of obtaining a specimen of a portion of the tumor is illustrated in Figure 8 and has recently been emphasized by Caro.[3] It is important to obtain both normal and pathologic tissue in the same section. The specimen is then bisected by the surgeon (and this step is essential) in order to orient the material in the desired plane for the laboratory technician.

This method has several distinct advantages. It allows the pathologist to study the transition between normal and pathologic tissue. This may be particularly important in such lesions as early Bowen's or Paget's disease, keratoacanthoma, squamous cell carcinoma, et cetera. Also, it may give the pathologist sufficient normal tissue to ascertain from which tissue the tumor originated. The technique, as illustrated, also permits the surgeon to pass his suture through normal, healthy skin, thus avoiding friable tumor tissue when attempting to close the surgical wound.

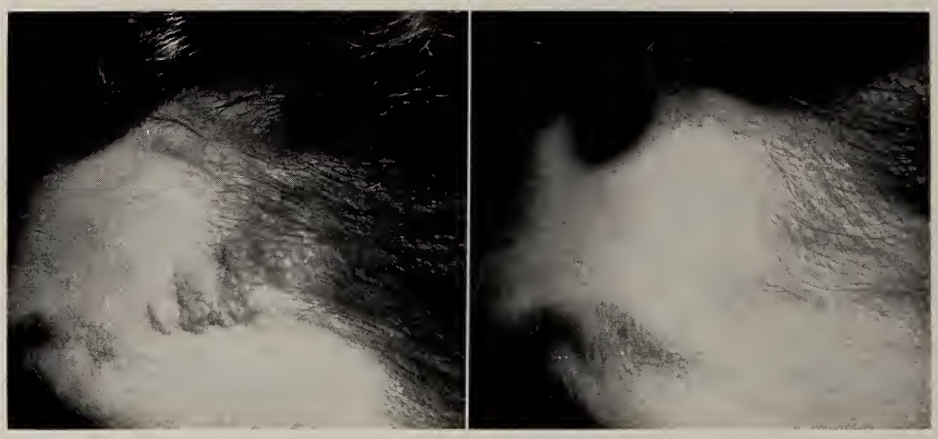

Fig. 9 *(left)*. Longest diameter of tumor (nevus sebaceus) positioned at right angles to wrinkle lines. In this instance, in the attempt to conserve normal tissue, the excision was performed perpendicular to the desired excision lines.
Fig. 10 *(right)*. End result following surgical excision of lesion pictured in Figure 9.

This method of including normal skin in the biopsy specimen is not universally accepted by dermatologists since some feel there is the possibility of incorrectly embedding the specimen during processing so that the sections are cut from the normal portion of the specimen with the result that the tumor is missed altogether. Such an error will be avoided when the pathologist and his laboratory assistants are alive to the problems of dermatohistopathology, and if proper precaution is exercised in preparing the specimen.

Finally the specimen should include tissue from the deepest portion of the tumor. This allows the pathologist to gain some impression as to the invasiveness of the tumor at that site.

Scalpel Surgery

There are some errors in technique which are seemingly common with the use of the scalpel in skin cancer surgery.

One such error is the poor selection of lines of incision to remove the tumor. The skin is under constant tension in all directions, but the magnitude of tension varies from one direction to another. It was shown by Langer[5] that when a round awl was used to produce circular holes in the skin at various sites of the cadaver, on removal of the awl the round defect immediately shaped itself into an oval. Langer then plotted these oval defects on anatomical charts and concluded that the longest diameters of these defects coincided with the directions of greatest skin tension. Langer's lines have been used for many years by surgeons in planning lines of incision for removal of skin specimens by elliptical excision. Although using different techniques Rubin[4] and Kraissel and Conway[5] came to the same conclusion that the time honored use of Langer's lines as longitudinal directions for scalpel incisions was incorrect for certain sites, particularly on the face. They pointed out the importance of taking into consideration the natural skin folds, wrinkle lines and underlying musculature.

However, no illustration of suggested lines for scalpel incision can include all the possibilities and the final decision must depend upon the clinical findings.

At times, the choice of the line of incision is influenced by the configuration of the tumor. For example, when the long axis of the tumor is in a direction which does not coincide with the lines

of wrinkle, it may be advisable to remove the lesion in a manner which conserves the most tissue even though the lines of incision are not in the preferred directions (Figs. 9 and 10).

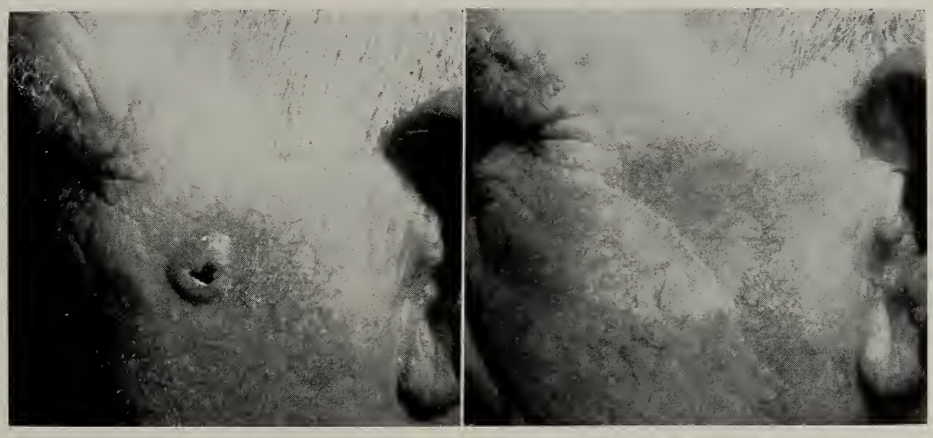

Fig. 11 *(left)*. Squamous carcinoma which was inadequately excised in its depth.
Fig. 12 *(right)*. Same patient as in Figure 11 two years following x-radiation of surgical site.

Another comparatively frequent error in scalpel surgery is inadequate depth of excision. Failure to excise sufficiently deep is evident on microscopic examination of the specimen. When this occurs and pathological tissue is left in the depths of the wound, the physician is often left with a difficult clinical and therapeutic problem since deep recurrences are hard to recognize clinically. If additional surgery is decided upon after examination of the specimen has shown the first excision to have been of insufficient depth, sacrifice of considerable more normal tissue must be made. When a lesion known to be radiosensitive is incompletely excised in its depth, it is often preferrable to employ subsequent irradiation rather than to resort to additional surgery. To illustrate this, Figures 11 and 12 show a squamous cell carcinoma of the malar area which was surgically excised but on reviewing the sections, it was apparent that the depths of the lesion had not been reached and some malignant tissue remained. For this reason, the patient was given x-ray therapy (5440 r in eight exposures of 680 r each at 100 K. V., 0.9 mm. Al.HVL over nineteen days) to the tumor site postoperatively. To repeat surgery in this instance would have necessitated sacrifice of a wide area of surrounding normal skin and subsequent graft.

In most instances of skin cancer surgery, if the incision is carried well into the subcutaneous tissue, the problem of incomplete removal of the deeper portions of the tumor can be avoided. Even though the lesion extends into the subcutis, careful inspection at the time of the operation will usually show a gross contrast between the tumor and the adipose tissue. This allows the physician to extend his procedure to include any macroscopically discernible tumor.

Desiccation and Curettage

The most frequently employed modality by far in the management of basal cell epitheliomas in our clinic and practice is electrodesiccation in conjunction with curettage. This method enjoys its popularity because of its many advantages including, among others, the following:

1. The principal advantage is that desiccation and curettage permits the surgeon to "seek out" tumor extensions with the curette. The physician experienced with the use of the curette can often clearly perceive the difference between normal and tumor tissue simply by the "feel" of the curette as it passes over the tissues. This ability to "feel one's way" through the tumor to its peripheral portions results in less sacrifice of normal surrounding tissue, and minimizes the danger of damage to underlying structures.

2. Electrodesiccation and curettage does not require the time-consuming sterile surgical set-up that is necessary for scalpel surgery.

3. The heat and coagulation produced by electrodesiccation provides hemostasis and dehydrates the tumor and normal tissue permitting thorough curettage in a relatively bloodless field.

As with any destructive procedure, desiccation and curettage also has its limitations. The curette alone generally provides a less desirable biopsy specimen in comparison with that obtained by scalpel or even scissors biopsy. Certain tumors are not suitable for treatment by desiccation and curettage, for example, sclerosing basal cell epitheliomas and deeply invasive tumors involving underlying cartilage or bone. In certain sites, desiccation and curettage may leave a poor cosmetic result such as on the skin of the upper lip, chest and back because of the tendency to produce lasting hypertropic scars in these areas. Wound healing after desiccation and curettage is considerably slower than that following surgical excision with primary closure. A final limitation of this procedure is that the curette cannot follow out thread-like microscopic tumor extensions.

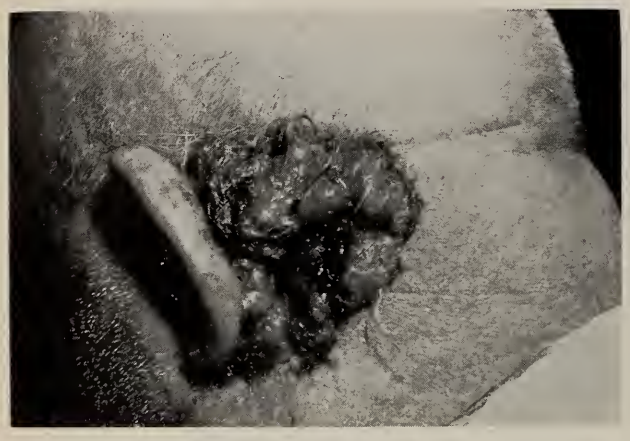

Fig. 13. Example of fungating basal cell epitheliomas in which bulk of tumor tissue should be removed by electrocutting prior to x-radiation.

When preparing the lesion for desiccation and curettage, it is advisable to mark the borders of the area to be treated with a dye (such as genitian violet) since skin landmarks may be obscured by the distension of the tissue resulting from the infiltration of the local anesthetic. The first step in the destruction of the lesion should be curettage since this gives the physician information concerning the consistency of the tumor before it is electrodesiccated. Malignant tumors are generally friable and the tissue can usually be curetted with ease. As a rule, the curette as it is drawn across the surface of the relatively firm normal skin "falls" into an area of soft cancerous tissue. Friability, then, lends weight to the clinical impression that the lesion is malignant. However it should be stressed that not all skin cancers are soft in consistency, and that certain non-malignant tumors (for example, some infectious granulomas) are of a consistency which is indistinguishable by the "feel" of the curette from skin cancer.

Bipolar Electrocutting Current

The electrocutting knife, loop and needle are successfully used as thermal "scalpels" for the removal of skin tumors. The electrocutting current has received only limited use in the treatment of basal cell epitheliomas in our clinic with a few exceptions. In certain fungating basal cell epitheliomas (Fig. 13) which are to receive x-radiation, the bulk of the tumor tissue extending above the surface of the skin is removed by the electrocutting current before irradiation is begun. Should the fungating tissue not be removed prior to irradiation, a large friable, malodorous, disintegrating mass results. This combined therapy is advisable since on the one hand, because of the invasiveness or extent of the lesion, it cannot be properly managed by electrodestructive procedures alone (for example desiccation and curettage) and, on the other, if irradiated, the resulting necrosis of the tumor would be extremely unpleasant for the patient for weeks thereafter. By combining the two methods, certain large tumors can be properly and well managed particularly in patients who are poor surgical risks or who refuse major operative procedures.

The advantage of the electrocutting current in this instance is that the coagulation of blood vessels prevents excessive bleeding simplifying the surgical removal of the bulk of the tumor.

Sherwell Method

The acid nitrate of mercury technique of Sherwell is employed in our clinic on selected patients for the management of basal cell epitheliomas.

In this procedure, the area is anesthetized and the lesion is removed by thorough curettage. It should be stressed that the curettage is the essential part of this method. Following the curettage, acid nitrate of mercury* is applied to the base of the defect and allowed to remain for five to twenty minutes. Finally a paste of sodium bicarbonate made by adding a small quantity of water to the powder is spread onto the area to neutralize the excess acid. Following this, a dry dressing

*Red oxide of mercury 40.0
Nitric acid 45.0
Water, to make 100.0

is applied to cover the paste. The dressing is left in position for several days and then changed as needed until the wound is healed.

Although there is no proof, the theoretical advantage of this procedure claimed by its advocates is that tumor tissue is considerably more sensitive to the destructive effects of the acid nitrate of mercury than the normal tissue and therefore if any tumor cells remain they are "selectively" destroyed. In addition, some proponents claim that the resulting scar is more pliable and therefore cosmetically more acceptable than that obtained with curettage only, but this too remains to be determined by long term observations.

Special Methods

Other surgical techniques used by dermatologists in the management of basal cell epitheliomas of the skin include circular punch full-thickness grafting procedures, chemosurgery (Mohs), and dermabrasion (in the management of "multicentric" superficial basal cell epitheliomas). These, and other highly specialized procedures are receiving increasing employment by those who have acquired the necessary skill in their application.

Role of the Dermatologist

The more experience one accumulates in the field of cutaneous oncology, the more precise become the indications for the management of each tumor as an individual problem. Therefore, it is not correct to say that a given modality *should* be employed for a certain group of tumors since many additional factors peculiar to the case must be taken into consideration. In relation to the *patient:* the age, sex, color, occupation, healing and scarring potential; in relation to the *tumor:* its history, site, pathology, radio-sensitivity, local extent and presence or absence of metastasis; in relation to the *physician:* his qualification, ability and facilities, these are among the most important features which play their role in the final decision of definitive therapy for the presenting tumor.

The dermatologist is in an ideal position to manage most cutaneous malignancies. His training and experience in the differential diagnosis of cutaneous disease, including skin cancer, puts him in the fore as a clinician. Among specialists, only he is equipped and trained to use any or all modalities (cold steel surgery, electrosurgery, chemosurgery, x-ray, use of radioactive materials, et cetera) commonly used in skin cancer therapy. This permits the necessary individualized approach to each presenting problem. Undoubtedly his knowledge and experience in differential diagnosis coupled with his versatility and elasticity in selection of therapeutic modalities places the dermatologist in an unexcelled position among specialists in the management of the majority of skin neoplasms. But it is only through his continued critical analysis of the results of the various therapeutic modalities employed in the management of cancers of skin that the dermatologist will be able to answer for himself the question, "What is the best method for treating a given skin cancer in a particular individual?"

Summary

1. Skin cancer is the most common cancer of man and includes a wide variety of neoplasms. A thorough understanding of the natural history and degree of malignancy of these lesions is prerequisite to intelligent management.

2. Most skin cancers are amenable to treatment with dermatologic therapeutic modalities, but each method must be given careful, renewed consideration for every presenting lesion.

3. Some common problems and procedures in relation to the dermatologic surgical management of basal cell epitheliomas of the face are discussed.

4. Surgical management of cutaneous malignancy remains highly specialized and requires clinical experience, surgical training in the various methods employed, and knowledge concerning the ultimate effectiveness and cosmetic result of the procedures used.

The material on basal cell epitheliomas of the face was presented in part at the Annual Scientific Session of the American Cancer Society, New York, October 29, 1957, and has subsequently been published in the proceedings of this meeting.

Correction of

THADDEUS J. LITZOW, M.D.
Rochester, Minnesota

A crooked or deformed nose is one of the most psychologically damaging facial blemishes. Proper correction of such abnormalities is gratefully received by the patient, whose entire outlook on life usually is changed by the improved appearance. Technics for correcting nasal deformities are illustrated here.

THERE ARE many nasal deformities that deserve correction to a normal appearance. Only occasionally a patient presents himself with a complaint of a nasal defect so small that whether to categorize his nose as abnormal or deserving of surgical correction depends on the examiner's personal aesthetic values. A goodly number of the nasal deformities are quite evident at first glance, and several examples of such cases will be presented.

One deformity that the patient usually considers an emergency is the immediate traumatic nasal fracture. Any physician may be called on to deal with this problem. If seen early after the injury, the nose can be examined easily before edema swells the soft tissues and makes inspection and palpation of limited value. Roentgenologic study can be helpful, but usually one relies on his clinical examination.

Fractured nasal bones that are not displaced require no special treatment. A properly applied nasal splint does no harm and serves as a guard against later displacement.

Displacement of fractured nasal bones can be reduced immediately, the patient's general condition permitting. Satisfactory anesthesia usually can be obtained by local application to the nasal mucosa of a suitable topical anesthetic such as cocaine. A fine instrument such as a small, blunt periosteal elevator inserted into the nasal cavities can apply

Nasal Deformities

Dr. Litzow is in the Section of Plastic Surgery, Mayo Clinic, Rochester, Minnesota.

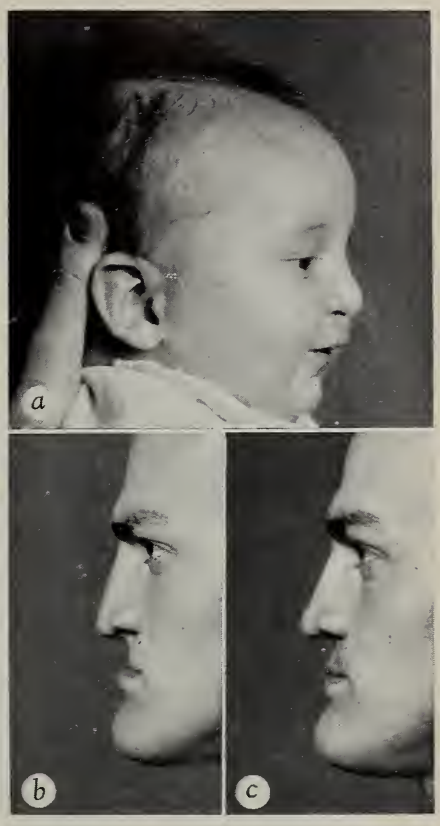

Fig. 3. *(a)* Shortened columella and depressed nasal tip after recent operation for bilateral cleft lip. *(b)* Uncorrected nasal deformity after repair of bilateral cleft lip. *(c)* Columella lengthened by advance of prolabium of upper lip, nasal tip assuming more normal position with satisfactory nasal profile.

pressure to reduce inward displacement. Outward displacement is reduced by direct external pressure. Inspection and palpation tell when the reduction is adequate. Then the nose is splinted for seven days.

Fig. 4. *(a)* Shortened central portion of the upper lip is prolabium used to lengthen columella. *(b)* Sufficient tissue from lower lip was transferred to fill defect previously occupied by prolabium and gave necessary added length.

A questionable nasal fracture with marked soft-tissue swelling requires checking from time to time until most of the edema subsides. Then an adequate examination of the supporting structures of the nose can be made with the assurance of correct diagnosis. If a fracture with displacement of bone is found, correction is accomplished as described above.

Treatment of the more extensive nasal bone fractures, injuries, and displacement of the nasal septum will not be discussed here. The reader is referred to standard textbooks of plastic surgery for further details.

If the displacement of fractured nasal bone is not reduced before healing, a permanent deformity follows, as illustrated in Figure 1a. Refracture with a sharp chisel and realignment are necessary to correct the defect (Fig. 1b). Selection of this patient or any patient for a cosmetic procedure demands close scrutiny. The criteria for rhinoplasty have been presented in full by Erich.[1]

Some deformities are marked, and the patients' desire for correction is strong. The deformity of the boy in Figure 2a was such an example, affecting both the osseous and the cartilaginous structures and requiring mobilization of both to obtain a satisfactory realignment (Fig. 2b).

The incidence of cleft lip or palate has been estimated conservatively as one in every thousand live births. It is not surprising then that the surgeon is called on frequently to close these defects

and correct the associated nasal deformities. Bilateral—and usually unilateral—cleft lips have nasal deformities characteristic to each.

The profile view of a recently repaired bilateral cleft in the lip of an infant demonstrates the shortened columella which pulls the tip of the nose down (Fig. 3a). A similar view of a repaired bilateral cleft lip in an adult with the still-uncorrected shortening of the columella is seen in Figure 3b. Advancement of the prolabium lengthens

Fig. 5 *above. (a)* Nasal deformity commonly associated with cleft in left upper lip repaired previously. *(b)* Nasal deformity corrected.

Fig. 6 *below. (a)* Large nose with hump and slightly drooping bulbous tip. *(b)* Early postoperative result.

the columella and gives a pleasing profile (Fig. 3c). An Abbe-Estlander flap from the lower lip replaces the advanced prolabium (Fig. 4a and b) and restores a more normal appearance to the upper lip. The profile of the lips also is improved with this method (Fig. 3c).

The nasal deformity associated with unilateral cleft lip usually consists of a widening and flattening of the nostril on the affected side (Fig. 5a), with corresponding flattening or depression of the adjacent aspect of the tip of the nose. The entire nasal deformity reflects the malformation of the alar cartilage accentuated by the lip cleft widening the base of the nostril or actually extending into the nostril. Repair of the nasal portion of the cleft-lip deformity requires closing of the cleft and narrowing of the widened nostril to conform to the opposite normal side. The deformed alar cartilage on the side of the cleft is reshaped to establish normal symmetry (Fig. 5b).

Fig. 7 *above. (a)* Wide nasal tip. *(b)* Nasal tip narrowed.

Fig. 8 *below. (a)* Rhinophyma. *(b)* Early postoperative result.

Probably one of the most commonly seen congenital deformities is the humped nose with a drooping bulbous tip and large over-all size. Usually a satisfactory correction can be accomplished (Fig. 6a and b). Correction of the bulbous tip is best demonstrated by special views such as Figure 7a and b.

The older patient having escaped the congenital or traumatic deformities may yet acquire nasal dimensions that need correction. Rhinophyma, a complication of acne rosacea, may increase the size of the nose to tremendous proportions. The tissue is pared down to proper size (Fig. 8a and b), usually in one operation.

Loss of soft-tissue covering of the nose can be restored by skin grafts and flaps. Usually a nose partially or entirely lost can be reconstructed by utilization of the patient's own tissues. If for any reason reconstruction cannot be done, a prosthesis can replace the lost tissues.

Asthma in Infancy and Childhood

Results of Allergic Management

A family pediatrician, not a pediatric allergist, reports his results of handling 208 allergic children under twelve years of age, eighty-one of whom had asthma. His methods of evaluating, treating and following these infants and children are reported.

The family doctor and the general pediatrician can do much in their own back yard with the management of allergic asthma in infancy and childhood.

STUART LANE AREY, M.D.
Minneapolis, Minnesota

ASTHMA is defined by Rubin[1] as "an allergic disorder of the respiratory system, characterized clinically by paroxysms of an expiratory type of dyspnea with wheezing, and anatomically by a generalized obstructive emphysema." Glaser[2] defines it as "a form of obstructive emphysema which involves both lungs. It is characterized by paroxysmal attacks of dyspnea chiefly expiratory in nature and is accompanied by wheezing heard on auscultation. It is typically relieved by sympathomimetic drugs." Such a definition is not all inclusive, inasmuch as patients under two years of age may have dyspnea on the inspiratory phase of respiration. They do not show the anxiety exhibited by adults or older children, and may be quite comfortable when flat on their backs. This is in contrast to older children and adults who seek relief by sitting erect.

Asthma may be confused with other conditions in infancy and childhood. Some of the common conditions mistaken for asthma are:

1. Mucus in the nose and throat
2. Enlarged adenoids with stertorous breathing
3. Retropharyngeal abscess
4. Relaxed epiglottis
5. Anomalies of the great vessels
6. Rarer narrowings of the respiratory tract: foreign body, tumor, lymphadenopathy
7. Cystic fibrosis of the pancreas
8. Nocardiosis
9. Laryngo-tracheo-bronchitis
10. Ayerza's disease
11. Localized hypertrophic emphysema

Most of these conditions, if they are thought of, can be ruled out fairly simply by appropriate laboratory, x-ray and physical examinations. A differentiation can be simplified by the fact that in nonasthmatic conditions there is no response to epinephrine, no post nasal eosinophilia, and no changes in the cells of the nasal mucosa which are characteristic of the allergic state as demonstrated by Bryan.[3]

Asthma of allergic origin is caused by an antigen, which may be inhaled or enter through the G.I. tract. This, in turn, reacts with an antibody on or in the sensitized cell, with the release of histamine and other chemical mediators, such as the slow reacting substance, 5-hydroxytryptamine, acetylcholine or heparin. These in turn react on the smooth muscle and the blood vessels of the shock organ.[4]

Flensborg[5] found that of 298 asthmatic children, 190 male and 108 female, under ten years of age, asthma was three times as frequent in boys as in girls. With nonspecific management, 40.3 per cent of the attacks ceased, 54.7 per cent still had attacks and 5 per cent or fifteen of the children were dead. Five of these children died in status asthmaticus, and ten of intercurrent disease not related to asthma. In 8.6 per cent, the attacks were more frequent, and 71.2 per cent the attacks were less frequent at the end of ten years. These children had been treated by allergic management without hypo-sensitization. Engstrom and Kraeplin[6] found that out of 110 asthmatic children treated with hyposensitization for two to four years, there was improvement noted in 84 per cent and absence of symptoms in 71 per cent. They empha-

Inaugural Thesis presented before the Minnesota Academy of Medicine, November 11, 1959.

size that the duration of asthma had no effect on the results and advised that treatment must be continued at least two years.

I should like to report on the results personally obtained with asthmatic children in a pediatric practice where allergy is done by an interested M.D. who does not limit himself to pediatric allergy. These results, I am sure, can be duplicated by any pediatrician who is willing to spend the necessary time with his patients. In order to do satisfactory work, one day a week was set aside for allergy patients. Each patient had a detailed history recorded following the outline proposed by Glaser[2] together with a complete physical examination, including x-rays of the chest and other pertinent laboratory work.

Intradermal tests were done after the method of Rinkel.[7] These tests included all of the pollens found in this area, house dust (Endo dust®), three of the common molds and a mold mixture consisting of twelve less frequently found molds. In addition, tests were done for the epidermal offenders: feathers, wool, cat, dog, goat, et cetera.

The often repeated statement that skin tests can not be done in infancy and early childhood is a canard. Technically it may be more difficult, but it is possible to do satisfactory tests at a very young age. Several of these patients were satisfactorily tested under a year of age. The reactions, however, seem to be less intense in infancy and more positive tests are obtained to foods than to inhalants. Scratch tests are done for foods which the patient may eat. Individual food tests are done for the most commonly implicated foods; some of these individual food tests were done in the office and others were done at home by the parents. These tests[8] are done by omitting the food to be tested for a period of at least four days, and not more than twelve days, and then feeding it at noon of the fifth day under controlled conditions. An increase of at least twice the frequency of cough, sneezing or nasal drainage constitutes a positive test. Foods implicated by history or scratch test were tested by direct feeding. I would like to emphasize the fact that slavish reliance on scratch tests for food sensitivity is most disappointing, inasmuch as Rinkel states that food tests in asthma show an accuracy of only 38 per cent.[8]

At the conclusion of the inhalant testing, the parents are given instructions in detail. It has been found satisfactory to talk to them while recording the instructions on a dictating machine, a copy of this is then incorporated in the patient's record and other copies are given to the parents and the referring physician. Liberal use is made of printed forms such as "methods of avoiding house dust." The problem of dogs and cats as pets for allergic youngsters is discussed. As you know, there should be no cats or dogs in an allergic household. Foods are not routinely tested by individual tests where asthma is strictly seasonal and there are no signs of food allergy. The symptoms which lead us to incriminate foods are: (1) the history of itching in the back of the throat or the roof of the mouth, (2) attacks occurring in the middle of the night, (3) a history of exacerbation of symptoms every two to three days unrelated to seasonal changes in the pollen count. Individual food tests usually done in the office are: wheat, egg, milk, and corn, these being statistically the most important food allergens. Others may be tested at home by the parents.

In addition, the parents are given instructions in allergic prophylaxis, such as rotating the diet, the need for tetanus toxoid, choice of vocation, and choice of climate. Finally recommendations for symptomatic therapy are given.

At the present, I should like to report on the results of the treatment of eighty-one children under the age of twelve years, of whom fifty-one were boys and thirty girls. During the period that these eighty-one were seen, a total of 208 patients with allergic symptoms severe enough to warrant a complete allergic workup were seen in this office. Asthmatic children, therefore, in this series constitute approximately 39 per cent of the allergic children studied. Of the eighty-one asthmatic children, fifteen had their onset before one year of age, and fifty-six had their onset before the age of five. In these eighty-one patients, forty-three were found to have some food allergy. These foods were distributed as follows: milk eleven, wheat ten, egg nine, corn nine, chocolate three, peanut three, orange juice two, pork two, beef two, strawberry two, walnut two, apple two, and garlic, peaches, tuna and tomato one each. The commonest inhalant allergen was house dust. Only four of the eighty-one patients did not react to Endo dust in a dilution of 1:1000. Fourteen of the patients did not react to ragweed even in a dilution of 1:100 intradermally.

I personally attempted to divide the patients under therapy into those showing marked improvement, those showing slight improvement, and those

unimproved or worse. Of these eighty-one patients, ten had been followed too short a time for valid interpretation or could not be traced; therefore, a total of seventy-one patients have been followed for an adequate period of time. Of these, forty-two were markedly improved, eleven were slightly improved and eighteen were unimproved. These eighteen included all who did not continue therapy and those who would not cooperate in the food testing. Ten of these eighteen patients did not cooperate for what was considered adequate therapy; that is, they did not do individual food tests or did not continue for adequate hypo-sensitization. Six took less than eight hyposensitization doses. This leaves a total of sixty-one patients, a number which is probably not statistically too significant, who received what I considered adequate therapy. Of these, forty-two or 68 per cent, were markedly improved, eleven or 18 per cent were somewhat improved, nine or 14 per cent were unimproved. It might be added parenthetically that only five of these patients had Cortisone or other steroid therapy and only one received long term steroid therapy.

In order to get the parents' reaction to allergic management, post cards were sent to all of these patients. These contained two questions under which they were given three choices.

1. The present status of the patient:
   (a) no asthma during the past year
   (b) asthma occasionally, not a serious handicap
   (c) asthma frequently, a serious handicap
2. Do you think allergic management:
   (a) helped a great deal
   (b) helped a little
   (c) was of no value

We received answers from fifty-eight patients. Of these thirty-five or 61 per cent felt they had received marked help from allergic management; fourteen or 24 per cent felt they were helped a little; six or 10 per cent felt they had received no help; three or 5 per cent did not answer this question. As to the present status, ten of the fifty-eight or 17 per cent had had no asthma during the past year; forty-one or 70 per cent had had asthma occasionally but not severely; and seven or 13 per cent were having severe asthma attacks.

Even with our present admittedly imperfect knowledge of allergic disease it is possible to help the majority of children with asthma. Can men interested in pediatric cardiology, psychologic medicine, nephrosis or cystic fibrosis of the pancreas, all of these being entities which are fairly commonly seen in the pediatric practice, point to any better results? In a much larger sense, the awakening interest of any pediatrician in allergic problems will lead him to an awareness of the many facets of allergy in his day to day practice, such as the night cough, relieved by removing a feather pillow; the diarrhea due to milk in a premature infant; the metamorphosis from a screaming colicky baby to a placid infant in a milk sensitive newborn; or the clearing of a severe eczema in a nursing infant by taking the mother off eggs—all of these things being done without a formal allergic work-up. The field of pediatrics is a rapidly changing one. Allergies are assuming a greater importance in pediatrics each year.

Summary

The results of allergic management in a series of eighty-one children under twelve years of age are reviewed. By the pediatrician's evaluation, 68 per cent were markedly improved, 18 per cent were somewhat improved, and 14 per cent were unimproved. By parental evaluation, 61 per cent received marked help from allergic management, 24 per cent received some help and 10 per cent were not helped. Fourteen per cent of the children were free of attacks for one year and 73 per cent were having mild asthmatic attacks not enough to be considered a serious handicap. Thirteen per cent were still having severe asthma.

Carcinoma of the Oral Cavity
Part II

JOHN H. LAMB, M.D.
DWANE B. MINOR, M.D.
Oklahoma City, Oklahoma

Methods of Radiation

It has been our experience in treating mouth cancer over many years that radium combined with roentgen rays has resulted in the highest possible cures with the lowest number of sequelae and recurrences in carcinoma of the mouth. By combining two qualities of radiation, a much higher dosage of radiant energy can be given to the involved tissues with less permanent tissue damage than is possible with one modality alone. This method was evolved by Lain and Roland,[7] our predecessors, after many years of treating external skin cancers with this means, as well as oral cancers. Quoting from Quick[18] on the treatment of oral cancer, "I believe it is better practice to employ two sources and qualities of radiation than over-extending one per given quantity of radiation. The normal tissues within any field will react less violently to a combination of roentgen rays and radium than one or the other source alone."

In discussing the combination of therapy with various physicists, it is felt that the time element of various daily doses of x-rays and the continuous treatment over four to seven days with radium gives the tissues much more chance to recover. It is also known that the erythema dose of radium and filtered x-rays in combination is much higher in the number of combined roentgens required to produce in erythema at one sitting than the use of either one modality alone.[9] It is felt that this is also a factor in the excellent cosmetic results.

Oral Hygiene During Treatment

Because of the large number of the newer antibiotics in existence today such as tetracycline, et cetera, it is felt that there is no great danger in causing a sensitivity to penicillin by its prophylactic oral use of 200,000 units tablets T.I.D. during the time the needles are in the mouth. The oral penicillin administration may be continued ten days to two weeks following removal of the needles if it is indicated.

Résumé of Treatment and Results—1949-1959

The fifty-four patients studied with follow-ups as to method of treatment and cure rates was a long, exhaustive procedure; but, a careful study of a smaller group of private patients can be instructive. In order to report these results, the use of Table III will make for brevity. There are certain rules in treating this type of case which seem more or less routine to one who encounters these problems regularly, but they will be enumerated and discussed here.

TABLE III. RÉSUMÉ OF TREATMENT
(1949-1954)

Method of Treatment	Number of Patients
Interstitial needles only	1
Interstitial needles +coned filtered x-ray +radium intra-oral pack	2
Interstitial needles +coned filtered x-ray	5
Interstitial needles +coned filtered x-ray + external x-ray	19
Intra-oral radium pack and diathermic removal	2
External filtered x-ray +coned filtered x-ray	4
Interstitial needles +coned filtered x-ray +external filtered x-ray +intra-oral radium pack	12
Radium intra-oral pack +coned filtered x-ray + external filtered x-ray	6
Intra-oral radium pack +external filtered x-ray	3
Total	54

There are very few areas in the buccal cavity which give a flat surface in which a given dose of x-rays and radium can be exactly uniform or homogeneous. It is known that through the years in our treatment some areas received a combined x-ray and radium dosage of well over 11,000 r., but when a cure is accomplished it is known that the tumor received at least a lethal dose of 7000 combined r's *in all areas.* The mucous membranes of the mouth can take a dose of 12,000 r. with a combination of x-rays and radium with safety. The x-ray was produced by 170 K.V. machine, HVL 0.5 to 1 mm. Cu., and the radium consisted only of the gamma rays of radium.

Part I of this article was published in the February number of MINNESOTA MEDICINE.

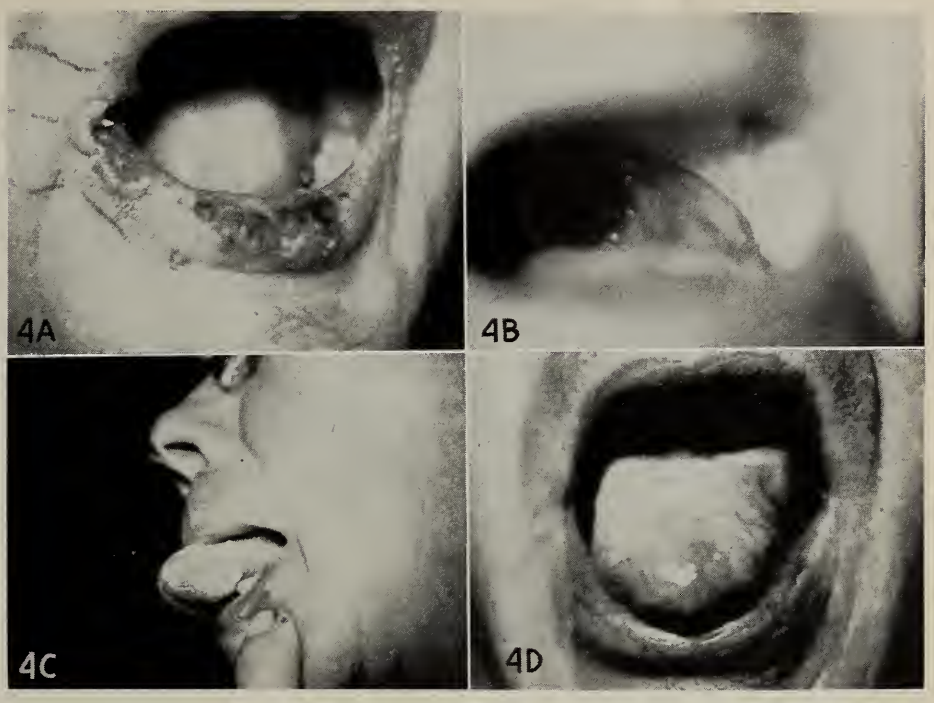

Fig. 4. (A). Squamous cell carcinoma involving two-thirds of the lower lip with extension 2.5 cm. into the commissure and the inner angle of the mouth and interdental buccal area (P_3N_0). Patient is a four-year cure with combined filtered x-rays in divided fields and interstitial radium. (B). Twelve-year cures in the left posterior tonsillar and upper posterior buccal areas with combined filtered x-rays, external radium application and interstitial needles. (C). Squamous cell carcinoma (P_1N_0) arising in leukokeratosis on the left side of the tongue. (D). Complete cure of the cancer and clearing of the surrounding leukoplakia with interstitial radium and combined filtered x-rays.

Carcinoma in the mouth usually occurred as a lump, a bleeding sore, or a verrucous, elevated growth of varying lengths of duration. The shortest time of duration was recorded as two months and the longest time was two years. The average duration in the fifty-four patients was 9.1 months. The lesion frequently was not tender, but the patient would complain of an irritation next to the dentures. Lesions of the gingiva have been known to grow extensively under fixed inlays. The size of the lesion varied in the fifty-four patients from 1.5 cm. in twelve cases, 2 cm. in eighteen cases, 3 cm. in twelve cases (all in the group P_1) up to 5 cm. in only two cases (P_2). Thus it is noted that the most frequent lesion seen in private practice was P_1 or, 1.5 cm. to 2 cm. in size.

In the more advanced lesions, the tumor may infiltrate deep into the intrinsic or extrinsic muscles of the tongue, or on the gingiva into the mandibular bone to produce erosion or destruction of the bone. The close proximity of these growths to the lymph nodes of the neck accounts for the ease of spread to these glands and makes it mandatory to include all the submaxillary areas in any treatment planning. The high rate of dissemination in oral cancer is best explained by Martin and Martin[20] by the fact that tumor emboli can easily be dislodged into lymphatic channels from a mouth which is almost constantly in motion, even during sleep. Hematogenous dissemination to distant sites is rare. In our fifty-four patients the usual site of metastasis was in the submaxillary region or deep, jugular chain.

There are numerous and varied surgical and radiation techniques by which these oral tumors are attacked at various treatment centers. The current surgical approach to this disease is one of resection of a block of tissue totally encompassing the tumor, including, at times, the adjacent bony structures such as the mandible or maxillae with a complete neck dissection. This method is a major surgical procedure and the great loss of tissue and deformity produced make it a very unpopular procedure with the patients; neither are the results dramatic as to cure.

In the failures to cure the growth by irradiation, these operations are then a necessity and sometimes after the highly malignant growth has been reduced in its malignancy by irradiation it is curable. The present-day radiation techniques in

our hands include the use of interstitial radium sources, intra-oral molds or "suckers" of gamma radium, and intra-oral and external x-ray therapy. There are very few areas in the mouth which

TABLE IV. RESUME OF RESULTS
(1949-1954)

Results of Treatment					
3 Year Cure	4 Year Cure	5 Year Cure or More	Death by Oral Cancer After Cured 5 Years	Lost Tract of	Deaths by Oral Cancer
1	1	37	2	1	14

5 Year Cure Rate=68.3%

lend themselves to treatment with one modality alone:

1. In the lateral buccal areas or at the intradental line the procedure was interstitial radium therapy (a dosage of 6000 r. to 7000 r.), plus intra-oral x-rays 170 KV HVL 1 mm. cu. with a cone (2400 r. or 240r.×10), and external x-rays to the gland-bearing areas (2400 r. or 240r.×10); (Fig. 3-C and D). Figure 4-A shows a squamous-cell cancer involving two thirds of the lower lip and a 3 cm. area into the right inner buccal mucous membrane. The cancer was entirely cured by the previously described method. Figure 4-B shows a nine-year cure in the left tonsillar and posterior buccal area by the same method.

2. To the tongue interstitial radium therapy plus intra-oral x-rays with a cone with external x-ray therapy to the submaxillary region was used (in the same dosage as previously described). Figures 4-C and D show a before-and-after picture of a cured squamous-cell cancer on the left anterior one-half of the tongue treated by the method described. Lesions on the posterior surface of the tongue which are difficult to reach with adequate homogeneous dosage of interstitial needles are treated, in addition to the interstitial needles, with intra-oral x-rays and a radium mold or "sucker."

3. The floor of the mouth is a very difficult area in which to space the interstitial radium needles properly and thus obtain a homogeneous dosage of gamma radiation. Thus, a mold or "sucker" of gamma radium is prepared to give an additional 2000 r. of gamma radium to this location. Intra-oral x-rays are added and both submaxillary regions are included in the external x-ray therapy. Care is taken not to overlap with too high a total dosage of x-rays in one given area when coned treatment is combined with external x-rays.

4. The gingiva: Interstitial radium needles are implanted on each side of the gingiva 1.5 cm. to 2 cm. apart, the surface of the growth is treated with an additional 2000 r. of external gamma radiation in the form of a mold, plus 3000 r. with intra- oral cone 2 cm. to 3 cm. in diameter, plus 2400 r. external x-rays to the gland-bearing areas.

Briefly, in summary, the dosages used successfully have been:

Gamma roentgens with interstitial radium needles 6000 r. to 8000 r. If the interstitial radium is not homogeneously distributed then gamma roentgens with intra-oral mold or "suckers" of 2000 r. are added, plus an intra-oral cone of x-rays, HVL 1 mm ca., 170 kv., 2000 r. to 3000 r.; plus external irradiation to the glands to a 6×8 cm. field kv., a total dose of 2400 r. to one field or, if crossfired, 1200 r. to each side of the neck. All x-ray dosage is given in divided doses over a ten-day period. The interstitial needles are filtered with 0.5 mm. platinum with distribution of 1 mg. per 1 cm. of active length of needle. They are spaced 1 cm. apart in tandem. In some areas in the oral cavity it is impossible to space the needles accurately and thus added gamma roentgens are delivered by external radium at 0.5 cm. to 1 cm. distance on an applicator. This is composed of two tongue blades taped together with 10 to 25 mg. of radium filtered with 1 mm. platinum distributed homogeneously at one end, covered with 0.5 cm. gauze and sealed with adhesive rubber and applied by the patient at home for two to three hours daily for a total dosage of 2000 r. These applicators are prepared and routinely tested by the Siemen's gamma roentgen dosimeter so an accurate dosage can be planned for each patient.

Table III shows a summary of methods used in the fifty-four patients studied; nineteen patients received interstitial needles plus coned x-rays and external x-rays to the gland-bearing areas; twelve patients received interstitial radium needles plus intra-oral radium "suckers" plus coned and external radiation to the submaxillary regions.

Of the fourteen patients who died of oral cancer, only four had had radiation by interstitial radium element needles (Table V). Two of these patients treated with interstitial radium were clinically well for five years after treatment, but had a new growth in another location in the mouth which was

TABLE V. SUMMARY OF METASTATIC DEATHS FROM ORAL CANCER

Sex	Average Age	Location		Syphilis	Metastatic Nodes on 1st Exam Size of Lesion		Biopsy		Metastatic Lesion at Death	
9 males	74	Left tonsilar	1	Wasserman (++++)[1]	P_1N_0	6	Refused	9	N_1	6
5 females		Gingival and roof of mouth	2		P_1N_1	4	Sq. cell Grade I	2	N_2	7
		Floor of mouth	4		P_1N_2	2	Sq. cell Grade II	2	N_3	
		Entire right of tongue and floor of mouth	1		P_3N_0	1	Sq. cell Grade IV	1	N_4	10
		Gingiva	2		P_3N_2	1				
		Tongue	4							

PREVIOUS CURE OF OTHER ORAL CANCERS IN THE SAME PATIENT

Case 15: Female Tongue Anterior: 1/3 cured P_1N_0 three years with radiation. Died with N_1—cancer junction of tongue and right pillar.

Case 21: Female Right Gingiva: P_1N_0 looked cured two years with radiation. P_1N_0 lived four years longer with surgery and radiation.

Case 40: Male Floor of Mouth: P_1N_0 cured with radiation five years, then P_1N_1 right side of tongue . . . Fatal.

Case 54: Male Left Tongue Luetic Leukokeratoses: Previous cures for oral cancer four years; with third cancer right tongue P_1N_1, radiation of the tongue cancer failed. Died with metastasis.

not cured by irradiation. The other ten patients were treated in conjunction with other physicians, and other methods, such as surgery and radon seed implantations, had been used first before the patients were seen by us. The size and location of the lesion made interstitial needles an impossibility in eight patients.

Our results of treatment are excellent. This encourages us to continue treatment in the oral cavity as we have been taught by our predecessors and by our own experience. Two cases showed a three-year and four-year cure respectively but died of other causes; thirty-seven patients were cured for five years or more with a five-year cure rate of 68.3 per cent.

Death from Oral Cancer

Death from oral cancer was recorded for fourteen patients. Table V gives a summary of these deaths. Nine patients were men and five patients were women. The average age was seventy-four years. In four patients cancer was located in the floor of the mouth, and in four patients it was on the tongue. These two locations have had the worst prognosis in our experience. The cancers involving the intra-dental line and the lateral buccal cavity did not produce a single death. One patient had syphilis with severe lingual leukoplakia and leukokeratosis. Seven patients out of the fourteen (50 per cent) that died with oral cancer failed to show any metastatic nodes (N_0) on palpation at the first examination of the lesion; four patients had one single unilateral node 2 cm. or less in size (N_1); three patients showed multiple unilateral nodes or one large, movable node more than 2 cm. in size (N_2). The size of the lesions in eleven cases (P_1) was less than 3 cm.; two patients were P_3, above 5 cm. in size.

Nine patients of the fourteen cancer deaths refused biopsy. The biopsies performed showed two patients with Grade I squamous cell lesions; two with Grade II squamous cell pathological reports, and one had grade IV squamous cell, carcinoma.

Six patients showed N_1 or a single node 2 cm. at death. Seven patients showed N_2 one large, unilateral node above 2 cm. in size, or multiple unilateral nodes. One patient showed N_3 bilateral nodes, and ten patients were reported with distant metastases before death (N_4).

Four patients finally died from another oral cancer after the original cancer was cured. These are shown in Table IV. One woman (Case 15), aged seventy-eight years, had a lesion on the anterior tongue which was arrested for three years with irradiation but died with a new cancer at the junction of the tongue and the right pillar.

The second case (Case 21), a woman, aged sixty-five, had a lesion on the right gingiva P_1 N_0, looked apparently well for two years following radiation, but had a new lesion in close proximity to the old one with metastasis P_1 N_1; however she lived another four years with conservative surgery plus radiation.

A third case (Case 40), a man aged seventy-eight, entirely recovered for five years by radiation to a lesion P_1N_0 in the floor of the mouth, only to develop a new lesion on the right side of the tongue (P_1 N_1) with a metastatic node. He died after palliation irradiation.

A fourth case (Case 54, Fig. 3-B), a man aged seventy-six, with a positive Wassermann, a history

of treatment with arsenicals and a deep leukokeratosis over the entire surface of the tongue, developed two cancers: one on the tip of the tongue which was cured with interstitial needles, and two years later another one in the center of the tongue which was cured by the same process for two more years. Then, after four years of apparent recovery from interstitial irradiation, a third cancer developed on the right side of the tongue. Because he was older and had less physical strength to endure the pain from another course of irradiation he went to a large cancer center which is not approved by the medical profession where he was treated for nine months with pills and tonics. He then returned to us. His lesion on the tongue was 2.5 cm. in size and a 2 cm. node in the right submaxillary area could be palpated. In spite of further radiation therapy to his tongue and the node he died.

A final case should be reported briefly to show that even a large metastatic node can be cured by external or interstitial irradiation. Case 12, a man aged sixty, had a large lesion P_2N_0 on the tongue. He was treated by interstitial radium needles, coned x-rays to the tongue, and x-rays to the submaxillary region. The lesion had been noticed for a year and involved almost the entire left half of the tongue. The patient had had leukoplakia on his tongue for fifteen years, had been a pipe smoker for thirty years, and had consumed alcohol to excess, until two years prior to his treatments. His serum showed a positive Wassermann reaction and he had received several years' antileutic therapy. All of these etiologic factors combined to make his prognosis for cure about 3 per cent, that is, excessive alcohol, syphilis and pipe smoking. However, he was an excellent patient and in six months his tongue lesion was entirely cured, but he developed a hard, indurated node in the left submaxillary region which was diagnosed clinically by us and by the surgeon as a metastasis from the original cancer. He refused surgery and received 2400 r. of x-rays with small fields to the lesion every six months for two consecutive times. The node gradually disappeared, he is still entirely well, and is being reported as a ten-year cure (1949 to 1959).

Conclusion

1. Twenty years of experience with the use of irradiation in cancer of the oral cavity are reported.

2. In a careful study of fifty-four cases of oral cancer (1949 to 1959), the results of treatment are tabulated.

3. Thirty-seven cases are reported as five-year cures; one a three-year cure, and one a four-year cure. This gave a five-year cure rate of 68.3 per cent.

4. In fourteen cases, the patients died with oral cancer and were the subject of discussion as to the method of treatment they received, the presence of palpable nodes on first examination, and other pertinent facts concerning these fatal cases.

Warts and Nevi

HAROLD G. RAVITS, M.D.
Saint Paul, Minnesota

Warts from viral infections and nevi as neoplasia constitute the most common epithelial tumors from the cradle to the grave. Their classification, recognition, and appropriate common-sense management belong to every practicing physician. Dr. Ravits here has presented a comprehensive and concise discussion of this common but frequently stubborn skin condition.

WARTS OR verrucae are benign, usually small circumscribed tumors. Warts are infectious and probably caused by a filterable virus. Autoinoculation of warts is a commonplace observation, and transmission of warts from man to man may be observed frequently. Their course and evolution are highly unpredictable, and often spontaneous cures occur, as well as cure by suggestion and psychotherapy. Simple measures will cure most warts and radical approaches should be reserved for more resistant forms and special situations.

Because of their different sizes, location, and numbers, treatment of warts must be individualized. For this reason, it is best to approach this subject with a classification of the various types.

Verruca vulgaris, common wart, or the so-called "seed wart," is usually seen on the extremities, especially the fingers. These warts are single or multiple. Children are more commonly affected. Those that occur under the distal margin of the nail plate are known as subungual warts and those that occur on the nail fold are known as periungal warts. Electrodesiccation is probably the treatment of choice for verruca vulgaris providing they are not too numerous. This is usually done very simply under local procaine anesthesia. The destruction should not be too deep because a wart is an intraepidermal growth. It is better to err on the side of not completely removing the wart than to destroy too much tissue and produce unsightly scarring. Electrodesiccation usually cannot be done if the warts are too numerous, or if they are in the subungual or periungual location. Under such circumstances chemical cauterization works the best even though this method sometimes may seem to be slow, tedious and not too precise. There are many chemicals in use either alone or in different combinations. Some of them are: trichloracetic acid, saturated solution of silver nitrate, pure phenol, 40 per cent salicylic acid plaster, 10 per cent formalin solution, 10 per cent salicylic acid in flexible collodion, and 0.7 per cent cantharidin in acetone and collodion. Freezing with such physical agents as carbon dioxide snow, liquid oxygen, or liquid nitrogen is also employed.

Flat warts or verrucae planae are smooth, flat, but slightly elevated. They appear chiefly on the face, neck, arms, and dorsa of the hands. This type is more common in children and young women. Often they are difficult to distinguish from lightly pigmented nevi. These lesions are frequently responsive to suggestive psychotherapy, reinforced with a mild exfoliative lotion or ointment such as used in the treatment of acne. An effective preparation is 5 to 10 per cent salicylic acid in alcohol or in an ointment base. Oral bismuth or mercury protiodide daily is of value. If these methods fail, very light superficial electrodesiccation can be done. This must be performed most carefully to avoid producing residual scarring.

Verruca plantaris, or plantar wart, may be present as one isolated lesion, or many lesions, on one or both feet. Multiple contiguous plantar warts forming a patch with a granular surface is known as a mosaic wart. These are the most difficult to treat. For the small isolated plantar wart, a moderate dose of superficial x-ray therapy is most useful. For non-responsive and larger lesions, chemical cauterants are most valuable. The following chemicals either alone, or in various

---

From the Department of Dermatology, Ancker Hospital (Dr. Harold G. Ravits, Director) and Division of Dermatology, University of Minnesota (Dr. Francis W. Lynch, Director).

combinations, are applied to the warts only: resin of podophyllin, trichloroacetic acid, monochloroacetic acid, bichloroacetic acid, salicylic acid in plaster or collodion, concentrated silver nitrate, cantharidin in acetone and collodion, and formalin. One must be wary of painful reactions; medications must be applied under medical supervision. These methods are time consuming and slow; much patience and time are required. Injections of novocaine into the base of the wart have been advocated as a method of therapy. Physical agents such as carbon dioxide snow, liquid nitrogen, and liquid oxygen have their advocates. Electrodesiccation must be used here with extreme caution because of the slow healing and scarring which might occur. Surgical excision of plantar warts is the final choice of treatment after all avenues of treatment have been exhausted. This is due to the risk of painful scarring. Thus the large variety of treatments for plantar warts attests to the unsatisfacory response of most of them.

Verrucae accuminata, condylomata accuminata, or moist warts occur in the moist intertriginous areas chiefly the anogenital area. Podophyllin is the treatment of choice. It is incorporated in either a 20 per cent solution in alcohol or tincture of benzoin. Treatment of painting medication on the lesion is performed every week until the wart is gone. Painful reactions should be watched for. In occasional instances of large condylomata, electrosurgery or other surgical measures are undertaken.

Pigmented nevus or common mole is one of the most common of all tumors. These nevi are not present at birth, but characteristically develop during infancy and childhood. A small percentage appear in adult life, and the vast majority of nevi are benign. Pigmented nevi usually begin as pigmented macules, but after months or years, they may become elevated and develop a variety of surface characteristics. The simplest way to classify nevi is by microscopic examination to determine the location of nevus cells in the skin. The flat macular lesions are of two types: (1) lesions showing increased deposition of melanin and a greater number of menalocytes at the epidermodermal junction, termed lentigo, and (2) lesions showing clumps or aggregations of nevus cells apparently being extruded from the epidermodermal junction into the underlying dermis known as junction nevus. A junction nevus is flat, smooth, dark, and hairless. It should be excised as it is thought to be a forerunner of malignant melanoma. A very, very small percentage of junction nevi become malignant. They may occur anywhere on the body but most commonly on the penis, palms and soles.

The intradermal nevus histologically shows the nevus cells to be aggregated entirely within the dermis. Clinically this is the so-called common mole which is flesh to dark brown in color, elevated, smooth, verrucous, or papillomatous. Hair is often present in these nevi and they are often seen about the face. These almost never become malignant.

The compound nevus resembles the intradermal or junction nevus and microscopically there are cords or nests of nevus cells in the dermis as well as at the epidermodermal junction. These are much more common in childhood and adolescence. It is very rare for a melanoma to arise from a compound nevus.

There are many reasons for removing nevi. Many are removed for cosmetic appearance. Most junction nevi should be removed prophylactically. However, they cannot be accurately evaluated without histological examination and we often have to rely on certain useful clinical guides. The following indications for prophylactic removal should be adhered to: (1) flat nevi in adults in which there is a color change, especially a redistribution of color so that it is speckled in appearance; (2) any nevus showing increase in size or contour; (3) any nevus showing ulceration, bleeding or crusting; (4) nevi located on genitals, hands, feet and mucous membrane; (5) when a nevus on any portion of the skin is subjected to repeated trauma.

The most effective useful and safe method for removal of nevi is simple surgical excision. Microscopic examination of excised tissue should be routinely performed. Radical wide excision of a benign lesion should not be done. A margin of 2 to 3 mm. of surrounding skin is usually adequate. If malignant change is found on microscopic study, radical excision should be undertaken.

Pedunculated, dome shaped or sessile lesions may be excised by curved scissors and the base cauterized by electrocautery. This heals leaving a nice cosmetic result, and a biopsy specimen is also preserved.

Blue nevus, epidermal nevus, and juvenile melanomas which are all benign lesions should probably be excised simply for prophylactic reasons especially if any aforementioned change occurs.

Dysgerminoma of the Ovary

Unusual Roentgen Manifestation of Metastases

S. B. FEINBERG, M.D.
Minneapolis, Minnesota

From the Departments of Radiology, Mt. Sinai Hospital and University of Minnesota Department of Radiology.

IN SPITE OF the fact that dysgerminoma of the ovary is known to all practitioners of medicine, the report, heretofore unrecorded, of a case with bizarre metastases from such a neoplasm is considered worthy of publication.

Dysgerminoma of the ovary is a rare lesion comprising approximately three per cent of primary ovarian malignancies.[1-4] The lesion can occur at any age, but is found most frequently in the second to third decades.

The lesion apparently originates from the anlage of gonadal cells before specific sex characteristics have developed.[1,2,5,6,7,8] The right ovary is more frequently the site of origin than the left. Bilateral involvement is not a rarity.[3,9] Metastases are primarily spread in a retrograde fashion via the lymphatic route.

Micropsy shows a lesion made up of round cells, with large deep staining nuclei and clear cytoplasm, which lie discreetly apart in an avascular stroma. The connective tissue trabeculae are diffusely infiltrated with lymphocytes.[4,6,7]

The cure rate has been reported to vary from 27.5 to 66 per cent.[2,3,4,9]

The purpose of this report is to summarize a case which exhibited heretofore unreported soft tissue, adjacent calvarial, and long bone metastases.

The patient also exhibited the more usual metastases.

Case Report

When first seen, the patient was seventeen years old and complained only about her enlarging neck. She was completely unconcerned about her abdominal enlargement which approached the size of a full term pregnancy. Her physical examination showed a large mass rising centrally from the pelvis and which extended to the subxiphoid level. It was smoothly marginated. The other positive physical finding was that of the classical "bull neck" described in Hodgkin's disease. Her admission chest examination (Fig. 1a.) showed massive superior mediastinal adenopathy. Her "normal" white blood cell counts were in the 3-4000 range. Her hemoglobin never rose above 9-11 Gm. Her bone marrow showed depression but no other abnormalities. In retrospect, she admitted she had never menstruated.

Radiographs showed the above mentioned mediastinal adenopathy (Fig. 1a.) and a pelvic mass with secondary evidence of retroperitoneal adenopathy manifested by ureteral displacement on her excretory urogram (Fig. 2).

The pelvic mass was surgically removed to facilitate radiation therapy, for the node biopsy showed dysgerminoma. The pelvic primary showed the same histology.

Fig. 2. Intermediate excretory urogram shows soft tissue mass arising from pelvis to L4 level with secondary moderate hydronephrosis to compression of distal ureters. In addition there is left ureteral compression and lateral displacement associated with tortuosity due to periaortic nodes. Note: this disappeared after surgery and irradiation.

Fig. 3. Pleural and subpleural metastases especially in left hemithorax, but they are also present in upper and mid lateral aspects of right chest.

Radiation with an HVL of 2.8 mm. Cu. was administered to the pelvis, periaortic bed, mediastinum, and cervical regions. The tissue dose varied between 600 r and 1000 r. The course of treatment was regulated by her white blood cell count which fell to the 1000 range and her hemoglobin which dropped to 3-4 grams. No masses were palpable after treatment. Her chest returned to normal (Fig. 1b.).

The patient was able to carry on a normal life during the next two and three quarter years in spite of multiple metastatic recurrences which were treated. She had a subcutaneous metastasis to the mastoid tip. Later she returned with pleural and subpleural metastases (Fig. 3.). During the last year she developed a large scalp mass and underlying fronto-parietal lytic and proliferative osseous metastasis (Fig. 4a., 4b.). There was a "sun-ray" type of new bone formation in this region. In addition she developed what looked like generalized facial edema. This too repre-

sented subcutaneous metastases. All of these responded to minimal doses of irradiation. Her last visits were because of a painful right hip which was actually due to a pathologic fracture through a generalized bone change involving pelvis, hips and femora. These zones showed marked demineralization, accentuation of the primary trabeculae, bowing of the femoral necks, and broadening of

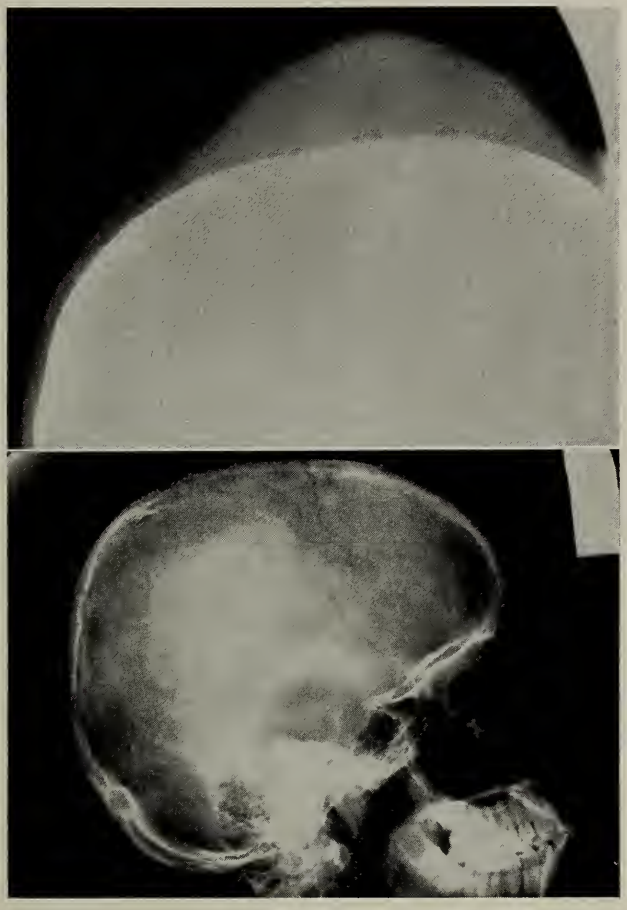

Fig. 4. (a) Soft tissue study of large scalp metastasis overlying the frontoparietal area. Note "sun-ray" new bone formation arising from the outer table of the cranial vault. (b) Routine skull projection showing bone resorption due to either true lysis or due to vascularity of tumor with secondary resorption.

the femora with some periosteal proliferation. The bone changes were pagetoid in appearance (Fig. 5.). She was treated with TEPA but did not respond.

Summary

The patient was a girl who was seventeen when first seen at which time she had a large pelvic dysgerminoma with periaortic, mediastinal, and cervical node involvement. The unusual features were the subcutaneous metastases which had the clinical appearance of edema. Her cranial vault lesion showed "sun-ray" changes. The pelvic and femoral findings were the most striking, for they had the appearance of advanced Paget's disease.

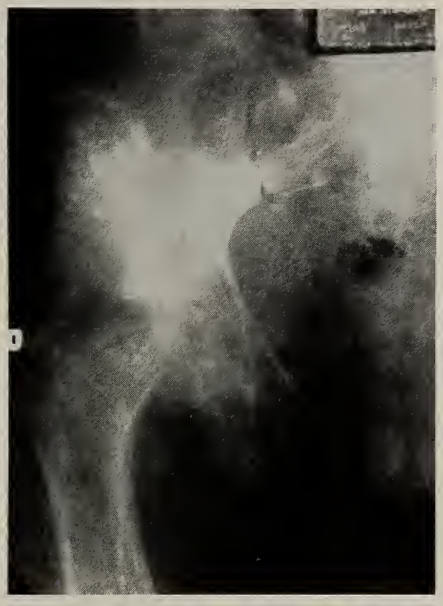

Fig. 5. Radiograph of right hip shows old impacted femoral neck fracture which is barely visible due to marked demineralization of the entire skeleton, especially pelvis and lower extremities. The most interesting feature is coarsening of primary trabeculae of bones, primarily of femora, with bilateral femoral neck bowing, pagetoid changes.

Birth Weight Disparity

A report on three sets of twins with marked weight disparity. The literature is reviewed and the authors discuss the possible etiology of this condition.

JOHN W. AUGHENBAUGH, M.D.
EDGAR G. INGALLS, M.D.
Minneapolis, Minnesota

Presented upon invitation by Doctor Augenbaugh at the meeting of the Minnesota Obstetrical and Gynecological Society, Minneapolis, Minnesota, November 29, 1958.

WITHIN a two-month period in the spring of 1957, Larson et al delivered three sets of twins which exhibited a marked disparity in birth weights. This disparity prompted us to search the literature in an effort to find out if there is a reasonable explanation for such a marked discrepancy in birth weights. This paper will consist of case reports of our cases along with some of the pertinent information found in the literature. We will include a few remarks about twinning in general.

Twinning has long been the object of special interest to lay persons and physicians alike, and the subject of many fanciful tales repeated by generations down through the ages. More recently, identical twins have been used in studies attempting to assess the relative contribution of heredity and environment to the development of the individual.

Twins are either monozygotic or dizygotic and twinning occurs approximately once in each eighty-nine births. Interestingly, the incidence of triplets is once in each 89^2 births and that of quadruplets once in each 89^3 births.[1] In general, about three-eighths of twin births consist of a male and a female infant. These sets are always dizygotic twins. Assuming that these represent approximately one-half of all dizygotic twin pairs, one could postulate that dizygotic twins make up six-eighths or three-quarters of all twin pairs and monozygotic twins the other one-fourth.

Two methods of diagnosing twinning with respect to zygotic origin have been widely used. These are the fetal membrane method and the similarities method. The former assumes that all monozygotic twins are monochorionic and that all dizygotic twins are dichorionic, and that careful microscopic study of the membranes will lead to a correct estimate of zygotic origin even if, as sometimes occurs, the two chorions are tightly fused.

The similarities method consists of comparison at a later date of such characteristics as physical appearance, blood types, eye color and fingerprints. When the two systems are compared retrospectively using the same subjects, one finds that they agree perfectly in cases in which the children are markedly dissimilar. However, in cases in which the children appear to be identical twins when measured by the similarities method, there is no agreement at all. Some authors feel that this is evidence that occasionally monozygotic twins have double chorions possibly due to twinning prior to the trophoblast stage. If this were so, then one could be certain of zygotic origin at the time of birth only in those cases in which a single chorion is present.[1,2]

Case Reports

Case 1.—A twenty-two-year-old Rh positive gravida 1 following a forty-week pregancy during which she had third trimester albuminuria ranging from one plus to four plus with a maximum blood pressure of 130/90, delivered a 6 pound 3 ounce living girl and a 3 pound 9 ounce living girl infant. The difference in birth weights was 2 pounds 10 ounces. The placenta grossly was of normal size with one cord inserted at the junction of the two amniotic sacs and the other in an eccentric position. Histologic examination of the placental membranes revealed the presence of a single chorion.

The smaller infant lived only three days. At autopsy the internal organs were found to be well developed and the lungs atelectatic. Microscopic examination of the organs revealed minimal hematopoiesis in the liver

and marked atrophy of, and hemorrhage into, the adrenal glands.

Case 2.—A thirty-one-year-old Rh positive gravida 3 para 2, following a thirty-six-week normal pregnancy with spontaneous onset of labor, delivered a 6 pound 6 ounce living boy and a 2 pound 7 ounce macerated stillborn infant. The difference in birth weights was 3 pounds 15 ounces. The placenta was markedly reduced in size and was grossly monochorial. Microscopic examination of the placenta was not performed.

At autopsy the stillborn infant was found to be macerated, poorly developed and poorly nourished. The abdominal wall was perforated, and a sizable segment of necrotic small bowel had herniated through onto the anterior abdominal surface. The internal organs were markedly necrotic and partially liquefield. Dissection and weighing of organs was not carried out.

Case 3.—A twenty-six-year-old Rh positive gravida 1, following a forty-week normal pregnancy, delivered a 6 pound 4 ounce living girl and a 3 pound 12 ounce living boy infant. The placentos were separate and were normal in appearance.

The smaller twin lived only one hour. Gross examination at autopsy revealed atelectasis, clubbing of the right foot, complete absence of kidneys, thrombosis of cerebral veins with encephalomalacia and calcification, and an area of subendocardial fibrosis. Microscopically the liver showed minimal hematopoiesis. Agglutination tests done on the mother were negative for toxoplasmosis.

When large numbers of infants are compared with respect to their birth weights, it can be shown that single fetuses weigh approximately 650 grams more than twin fetuses. This difference is due to a differential growth rate between twenty-seven and thirty-six weeks gestation. Physiological differences also exist in the birth weights of members of a twin pair, and are affected by differences in the duration of pregnancy, sex and zygosity. Dizygous male infants which are products of a full term pregancy tending to be larger. This average weight difference between twins is 400 to 500 grams.[3]

Brody reported four cases similar to ours, in three of which marginal insertion of the cord was found, and in one of which vellamentous insertion of the cord was present. He feels that the increased pressure on the placental vascular bed near term reduces nutriment to the fetus and that this reduction may be significant in twin pregnancies, where it occurs earlier. He also believes that this increased pressure has a more detrimental effect upon an infant whose cord is inserted at the thinner periphery of the placenta than on one whose cord is inserted at the thicker central portion. On the other hand, Eastman and Greenhill state that marginal insertion of the cord has no clinical significance.[4]

In monozygotic twins, when the two members of the pair begin to invade the common placenta with their blood vessels, they tend to divide the placental area somewhat equally. An extensive capillary anastomosis occurs between the two portions of the placenta. However, occasionally, in addition to capillary anastomoses, there occurs extensive anastomosis of artery to artery and vein to vein. Whenever there are anastomoses of this sort, much of the welfare of the twins depends upon whether such unions are symmetrical or asymmetrical. A symmetrical situation involves a fair and even exchange of blood between twins and all is well with both. But if there is an imbalance, one twin may progressively lose blood while the other progressively gains blood. Often the twin who loses blood dies and the circulation of both twins continues for awhile through the labor of the surviving twin, whose heart enlarges to meet the extra work load.[1,2]

Most authors agree that superfetation in a human has so far not been proved, although it has been well demonstrated in animals.[1] As you may recall, the living infants in our series upon whom autopsy was later performed had reached a state of development compatible with a full term pregnancy, a fact which would cast doubt upon superfetation as an etiological factor in these cases.

In summary, this paper has reviewed the case histories of three sets of twins showing marked differences in birth weight and has discussed several possible etiological factors.

Insect-Borne and Animal-Borne Virus Diseases of Man

CARL M. EKLUND, M.D.
Hamilton, Montana

From the U. S. Department of Health, Education, and Welfare, Public Health Service, National Institutes of Health, National Institute of Allergy and Infectious Diseases, Rocky Mountain Laboratory, Hamilton, Montana.

IN RECENT years, in countries outside the United States many new viruses which cause disease in human beings have been isolated from wild animals, and the geographic range of some viruses already known has been found to be greater than previously suspected. Although the situation has not changed appreciably in the United States within recent years, American travelers may encounter some of the newly recognized agents in other countries. The study of viruses isolated from wild animals, their maintenance in nature, and the diseases caused by them, has begun to comprise a field all its own.

The isolation and study of viruses from domestic animals has disclosed some interesting interrelationships with viruses considered to be limited strictly to human beings.[1-4] Fowl plague virus and two virus strains, one from sick ducks and the other from horses, isolated in Czechoslovakia, have been shown to be related to influenza A virus strains isolated from human beings. Andrewes[1] believes that the recent outbreak of the Asian type of influenza may have had its origin in some animal species in China. Recently it has been shown that a virus isolated from calves with shipping fever is related to the so-called hemadsorption virus I or para-influenza virus 3 isolated from children with respiratory illnesses. The virus of dog distemper shows a relationship to that of measles. In most of these instances, it is probably a case of viruses having a common origin some time in the past rather than of one virus strain affecting both animals and man.

The incidence of known virus disease acquired from animals in the United States is not great and varies widely from year to year. Tick transmitted virus diseases tend to be endemic; each tick season regularly produces its annual quota of disease. Mosquito transmitted virus diseases tend to be erratic in occurrence and may be of little importance for many years and then occur in epidemic form. The most common methods of infection are by arthropod vectors such as ticks or mosquitoes or by the respiratory route. Other methods are by bite of animals as in rabies, scratch in cat scratch fever or contact as in milkers' nodules.

A complete survey of this field would be a suitable subject for a symposium. I will confine my discussion to a small number of diseases which for various reasons have interested me. A short discussion of Q fever will also be included. This is because rickettsial diseases are usually considered with virus diseases, their reservoir is in animals and essentially the same technics are used for their study both in the laboratory and the field.

Mosquito-Transmitted Encephalitis[5]

Three of these diseases are recognized in North America. As far as is known, only two need be considered in the Midwest; that due to the Western equine encephalomyelitis virus and that due to the St. Louis encephalitis virus. The Eastern equine encephalomyelitis (EEE) virus has caused disease among horses primarily along the Atlantic and Gulf Coasts of the United States. In the interior of the country there have been outbreaks of EEE described in Ontario and Michigan and sporadic cases in Wisconsin, Missouri and Tennessee. Human disease has been recognized in Massachusetts, Louisiana, New Jersey and Texas. At the Rocky Mountain Laboratory, we have never

found any evidence of the presence of EEE virus in North Dakota, and it appears unlikely that it is any problem in Minnesota.

Encephalitis due to the *Western equine encephalomyelitis (WEE) virus.*—Encephalitis occurring simultaneously in people and in horses during the summer months in the western United States is almost certainly due to this virus. Outbreaks occur at irregular and unpredictable intervals. 1935 through 1938 were years with a high incidence of disease among horses. Disease in human beings began to be recognized in 1937. In 1941, a very severe outbreak involving particularly the states of North Dakota, Montana, and Minnesota occurred. Since that time there have been no severe outbreaks although it is a rare summer when no human cases are detected. The summers of 1947, 1949, 1953, and 1954 showed some increase in incidence in eastern Montana, North Dakota and adjacent Minnesota.

Whenever this disease occurs, there is an abundant *Culex tarsalis* population and WEE virus is readily isolated from this mosquito species, which has been established definitely as the only important vector. Present evidence indicates that a cycle of infection between *C. tarsalis* and wild and domestic birds is an important mechanism for maintaining the virus during the summer months. This mosquito commonly feeds on birds; WEE virus has been isolated from bird blood and antibodies against this virus have been found frequently in bird sera. In the laboratory, experimentally infected birds have a high titer of virus for a few days and can readily infect *C. tarsalis*. There is no evidence that the horse, or other large domestic animals, plays any role in spreading the virus.

How the virus is maintained from year to year in areas such as the northern United States where the winters are cold is not known. It has been suggested that the virus is introduced each spring as a latent infection in migrating birds; also, that hibernating *C. tarsalis* may carry virus through the winter. There is no substantial evidence for either hypothesis and there may be some mechanism for virus maintenance independent of both bird and mosquito.

Control in the horse population is simple since there is an effective vaccine. With regard to the human population, the attack rate, except in the 1941 epidemic, has not been high enough to warrant advising vaccination as a method of control. Where the disease is endemic and the population dense, as in the central valley of California, mosquito control is used and helps to reduce the incidence. In other areas, it has generally been left to the individual to protect himself against mosquitoes, which is not as unsatisfactory a method as it may sound. Disease does not occur without an abundant *C. tarsalis* population. A marked increase in mosquito population appears some weeks before human disease and, if observation of the *C. tarsalis* population is maintained, it is possible to give warning of possible danger and advise use of all possible methods of protection against mosquito bite.

St. Louis Encephalitis (SLE).—In the northern plains area of the United States only sporadic cases of this type of encephalitis have occurred. Surveys show a low incidence of antibodies in sera of people living in Minnesota, North Dakota and Montana. In Idaho, about 20 per cent of sera have SLE antibodies and virus is rather frequently isolated from mosquitoes, but actual clinical disease appears to be infrequent.

In North Dakota, Idaho, eastern Washington and California, most isolations of the SLE virus are made from *C. tarsalis* and this appears to be the important vector. In Texas, epidemiological evidence and isolation of virus indicate that *Culex quinquefasciatus* may be the carrier and in the central United States epidemiological evidence indicates that *Culex pipiens* is the important vector. Virus has been isolated from this species in a number of areas. Maintenance of this virus is not as well understood as that of WEE. Since *C. tarsalis, C. quinquefasciatus,* and *C. pipiens* all feed on birds, and since antibodies have been found in bird sera, and virus has been isolated from wild birds, it has been thought that a mosquito-bird cycle may be important in maintenance. However, during the summers in which WEE virus is found frequently in *C. tarsalis* and when there is ample evidence of a bird-mosquito cycle, conditions are not particularly favorable for epidemics of SLE.

The occurrence of St. Louis virus does not have any relationship to that of the WEE virus; the opposite would be expected if its natural history were similar. SLE virus does not produce clinical disease in the horse although antibodies against this virus are found quite frequently in horse sera. Also, there is no epidemiological evidence to in-

dicate that horses or other large domestic animals play any role in disseminating SLE virus.

Methods of control other than mosquito control have not been devised; there is no vaccine.

Diagnosis of both Western equine and St. Louis types of encephalitis should be established by laboratory methods since there are other types of central nervous system disease with similar symptoms. The simplest and most useful technique is the complement fixation test for which acute and convalescent blood specimens are necessary. A four-fold rise in antibody titer is considered diagnostic.

Tick-Transmitted Virus Diseases

Colorado Tick Fever (CTF).[6]—This is the most common tick transmitted disease of man in the western United States and is the only tick transmitted virus disease recognized in North America.

All patients with this disease have had exposure to ticks within the range of *Dermacentor andersoni,* usually four to five days prior to the onset of their disease. This is the common spotted fever tick of the mountainous areas of the western United States.

The virus is isolated readily from adult ticks and has been found quite frequently in engorged larvae and nymphs and their small mammalian hosts. It is maintained by a cycle of infection between immature stages of the tick and their host animals.

Persons commonly affected by CTF are sheepmen, cattlemen, foresters, fishermen, tourists, and others whose occupational or recreational activities bring them in contact with ticks.

The disease often has such a typical clinical course that the diagnosis can be suspected. There is sudden onset with fever, chilly sensation or chills, low backache, headache, and general aching. These symptoms continue for two to three days and then recur for one to three days. A marked leucopenia is characteristic. Occasionally encephalitis or marked bleeding occurs, usually in children.

Diagnosis is most quickly established by isolation of the virus from blood by use of suckling mice. Complement fixing and neutralizing antibodies appear in three to four weeks.

Control at present is through avoidance of ticks and the use of tick repellents. Current attempts to make a vaccine appear promising.

Powassan Encephalitis.[7]—Recently McLean and Donohue reported isolation of a virus from the central nervous system of a boy dead of encephalitis at Toronto, September, 1958. His home was Powassan, Ontario, about 200 miles north of Toronto. This new virus was said to be related to that of Russian spring summer encephalitis (RSSE) as shown by hemagglutination inhibition and complement fixation tests. This aroused considerable interest since RSSE is an important tick transmitted disease in Russia, Poland, Czechoslovakia, Yugoslavia, Austria, Sweden and Finland. Goats also may be infected by tick bite, have fever for a few days, and excrete virus in the milk which is infective to people drinking it. In Scotland and the northern counties of England a similar tick transmitted virus causes Louping Ill of sheep and occasionally affects human beings. Another similar tick transmitted virus causes a hemorrhagic disease in parts of Russia and India.

At the Rocky Mountain Laboratory preliminary study indicates that any relationship of Powassan to the RSSE virus is quite slight and field study by Kohls of the Rocky Mountain Laboratory suggests that ticks may not be involved in transmission to man. However, some other arthropod, such as a mosquito, may be the vector, and study is necessary to determine the importance of this new virus as a cause of human disease in the United States and Canada.

Disease Spread by Contact

Cat Scratch Fever.[8]—This is a clinical and epidemiological entity, although no etiologic agent has been demonstrated. No organism has been cultured and no disease has been produced in the common laboratory animals nor changes observed in tissue culture. Cat scratch fever is generally considered to be a virus disease. Some patients show a low complement fixing titer with Lygranum antigen, and on this basis attempts have been made to classify this disease with the lymphogranuloma-psittacosis group; but the evidence presented hardly justifies this conclusion.

Although in other countries some cases have been reported to be associated with injuries by thorns and wood splinters, most of the cases reported from Canada and the United States have been associated with cats.

In about 50 per cent of the cases, a few days after a scratch or other skin injury, a small reddish nodule appears at the site. On top of this

a vesicle, pustule, or crust may appear. Four to thirty days after skin injury enlargement of a regional lymph node is noticed. At this time there are usually mild systemic symptoms consisting of fever, headache, general aching and lassitude. Lymph nodes are frequently described as being as large as golf balls. A lymph gland may break down and become filled with pus. The adenopathy generally lasts from two to six weeks. A striking form of the disease is oculo-glandular: a granulomatous lesion of the conjunctival surface of an eyelid with marked swelling of a preauricular lymph gland. The groups of glands most commonly involved are the epitrochlear, axillary, cervical and inguinal.

Occasionally a case of cat scratch fever is complicated by encephalitis, but, fortunately, no sequellae appear to result.

The histological picture found in a lymph node does not differ particularly from that in other granulomatous conditions. There is first hyperplasia of reticulum cells, then areas of necrosis bordered by epithelioid cells in a palisade arrangement with an occasional Langhan's type giant cell.

Diagnosis in suspected cases is established by a skin test using pus from a fluctuant node of a known case. The pus is inactivated by heating to 60° C for one hour on three successive days and is usually diluted 1:5 with saline.

The disease appears to occur wherever there are both cats and an interested person looking for the disease.

The role of the cat is generally considered to consist of passive transfer of an agent acquired from some bird or mammal on which cats prey. Cats do not give a positive skin test and autopsy of some that have transferred infection showed no lesions. With the great number of virus agents now being found in the intestinal tract of various animal species, it seems possible that cats will be shown to harbor a virus harmless to themselves but pathogenic to man.

Milkers' Nodules.[9,10]—Becker, in 1940, was the first to publish an account of this condition in the American literature. The disease appears to be relatively common in dairy areas of the United States. The etiologic agent is considered to be a virus but is not vaccinia. A person immune to vaccinia is not immune to this disease and a person who has had milkers' nodules is not immune to vaccinia.

A patient presents himself with a bluish dome-shaped lesion 1 to 1.5 cm. in diameter on finger, hand, wrist or face. The lesion starts as a small red papule which slowly increases in size, lasts four to six weeks and causes little discomfort. The patient usually milks cows and often has recently started to do so.

There is usually a history of lesions on cows' teats. They start as small papules which become pustular or crusted, then a granulating ulcer appears which takes about two weeks to heal. Our limited attempts to demonstrate the etiologic agent have been unsuccessful.

B Virus Encephalitis.[11-13]—In 1934, fatal ascending myelitis in a physician following bite of a rhesus monkey was reported. In 1949 a case of fatal encephalomyelitis in another physician followed possible contamination of a cut on a finger by saliva of a rhesus monkey. Both physicians were engaged in experimental work with monkeys and, since up to that time no great number of people were engaged in such work, the disease was not considered to be a serious medical problem. However, since production of poliomyelitis vaccine began, large numbers of monkeys have been imported and many people are exposed. Recently, in connection with production of vaccine, one death from encephalitis in Canada and three in the United States were reported. In three instances there was history of recent contact with monkeys but no recent bites; in the fourth case there was handling of monkey kidney cells and a history of a recent cut by a broken bottle containing cells. B virus frequently has been isolated by laboratories doing large amounts of monkey-kidney tissue culture work, so it is known that both rhesus and cynomolgus monkeys are frequent carriers of the agent. In these recent cases, except for the patient cut by glass, the route of infection is not clear.

The virus is classed as one of the herpes group but is distinct from herpes simplex virus of human beings.

Air-borne Spread

Psittacosis (Ornithosis).[14-19]—A virus first thought to be limited to psittacine birds has been shown to be one of a group of closely related viruses affecting a wide variety of birds and mam-

mals. In 1953, Bedson stated that at least seventy species of birds belonging to ten orders had been shown to harbor infection. Similar viruses found in mammalian species are the pneumonitis viruses of mice and hamsters, the meningopneumonitis virus possibly originating in the ferret, and the viruses of bovine enteritis, bovine encephalomyelitis, sheep pneumonitis, enzootic abortion of ewes and a paralytic disease of opossums. There are two published reports of mammalian strains of virus causing disease in human beings, both were laboratory acquired infections. One was due to the virus of enzootic abortion of ewes, the other to the virus of bovine encephalomyelitis. The clinical picture in these two infections did not differ essentially from those caused by avian strains. At the Rocky Mountain Laboratory, Lackman, using a psittacosis antigen, has found a complement fixation titer of 1:16 or higher in 46 per cent and 69 per cent respectively of the sera of two bands of sheep. A more usual rate is 8 per cent. In one group of sera from forty-two Idaho sheepherders, seven (16.7 per cent) had complement fixation titers of 1:16 or higher in comparison with 2.5 per cent in a large group of sera sent in for various diagnostic purposes. Whether the antibodies found in the sheepherders' sera are the result of exposure to psittacosis infection in sheep is at present unknown but the possibility needs investigation. The existence of human strains causing atypical pneumonia has been suggested occasionally where there was no known animal exposure and especially where there was case to case transfer of infection. With the recognition of members of this group of viruses in an ever increasing variety of animals, it is best to be cautious about postulating an atypical pneumonia agent of this group with man as the primary host.

Nature of these agents.—Their uniform susceptibility to the action of penicillin and the tetracyclines and of some strains to the sulfonamides sets them apart from the true viruses. They are usually classified midway between viruses and rickettsiae.

Terminology and classification.—Available data have not permitted a satisfactory grouping of these agents. Strains isolated from non-avian sources, with the exception of meningopneumonitis virus which may be an avian strain, have not been pathogenic for birds so that a rough separation into avian and non-avian strains may be possible. Avian strains, however, have differed markedly as to virulence for experimental animals, toxin production and reaction in cross toxin neutralization tests. Therefore, it is impossible from a study of a strain to classify it in relation to a particular avian source. Mammalian strains, although isolated from the same animal species, show differences in virulence for experimental animals and in serology. A systematic study of these agents, to find some method of classifying them, is badly needed. The terms used such as trachoma virus, the virus of enzootic abortion of ewes, or psittacosis virus are not likely to suggest to one unfamiliar with the field that a group of related agents is concerned and a more informative terminology is necessary.

Maintenance of these agents.—Although much is known about the maintenance of these agents in birds, in aviaries, and in domestic birds such as pigeons, ducks, chickens, and turkeys and their transfer from such birds to human beings, little is known about the maintenance of such viruses among wild birds and their possible transfer to man either directly or directly via domestic birds. The natural history of the mammalian viruses has not been intensively studied, but latent infections are known to occur with some of them.

Q Fever.[20-22]—Although Q fever rickettsiae have been isolated from several species of ticks, human disease is rarely, if ever, caused by tick bite. Q fever rickettsiae appear to have established a cycle of infection in cattle, goats and sheep which is independent of ticks. The placenta and birth fluids of infected animals contain a large number of rickettsiae. Since these organisms are very resistant to drying, air-borne spread to uninfected animals seems likely. Any human beings in the vicinity can also become infected. Q fever in people working with sheep is definitely related to lambing time. In people exposed to infected cattle, the exact route of infection is not quite so clear since calves are born throughout the year in dairy herds and milk, which also contains rickettsiae, is often used raw. In southern California, it was definitely shown that there was a risk associated with working in a dairy, living near a dairy and, apparently, drinking milk containing viable rickettsiae. This latter point is not quite so clear since the people drinking raw milk frequently worked in a dairy or lived near one. In

England, spread from cattle has been attributed mainly to drinking raw milk. In packing house outbreaks spread appears to be air borne, but the tissue that is the source of infection is not known. These outbreaks are unusual in that for years great numbers of cattle and sheep may be handled without any trouble, and then a sudden outbreak occurs. The disease has been reported among people handling wool and among laundry workers handling soiled clothes from a laboratory working on Q fever.

The epidemiology of this disease is far from clear. In reports of any large series of cases, there is always a large group that does not have occupational contact with cattle or sheep or their products and does not consume raw milk. Some of these cases are attributed to contact with people who do have contact with cattle or sheep, for example, cases in barbers, shopkeepers, or bartenders; others to air borne spread at quite a distance. If these observations are true, the number of rickettsiae necessary to infect a human being is very low.

A major problem in the epidemiology is the role of dairy cattle. Infection of dairy cattle is known to be present throughout most of Canada and the United States. What is the public health significance? Some data indicate that ingesting rickettsiae is not very apt to cause disease so that it is questionable whether consuming milk which contains rickettsiae plus antibodies is very dangerous. The placentas of cattle have a high concentration of rickettsiae—are they much of a source of infection?

Wherever there are cattle, sheep or goats, the possible presence of Q fever must be considered. Infected animals have no symptoms of disease so that infection must be detected either by antibody surveys or by isolation of rickettsiae. In the United States, California has reported by far the largest number of cases because of the intensive study there by a number of investigators. Idaho probably is second in reported incidence, this being due largely to the long continued interest of Stoenner of the Rocky Mountain Laboratory in Q fever in southern Idaho. After a low level of incidence there for several years, a sudden increase to ninety-three cases occurred in 1958; this year (1959) the incidence is back to a more usual twenty-five cases. The cause for that sudden increase is not clear. Some of the other states in which infection, either in people or cattle, has been reported are Arizona, Iowa, Wisconsin, Ohio, Pennsylvania, Montana, New York and Massachusetts. Luoto, of the Rocky Mountain Laboratory, collected data indicating infection in thirty-five states, but little study has been carried out in the other states. In the Midwest, he states, infection has been reported in cattle in Minnesota and South Dakota, in addition to Iowa and Wisconsin.

The significance of the isolation of rickettsiae from birds and the demonstration of antibodies in their sera is not clear. Human infection has not been traced to birds.

Diagnosis of human disease must be made by laboratory methods since the disease does not differ clinically from diseases such as brucellosis or influenza. The complement fixation test is usually used; a four-fold antibody rise between acute and convalescent sera is considered diagnostic.

The disease has a relatively long incubation period of fourteen to thirty days. There is usually sudden onset with fever and chills or chilly sensation. During the course of illness, headache and poor appetite are common, as well as general aching and profuse sweating. Fever may last from two days to three months but duration beyond three weeks is exceptional. Although respiratory involvement is frequently emphasized, it was not prominent clinically in the California experience. The signs usually consisted of dry unproductive cough and some rales on physical examination. Pulmonary lesions were found in 28 per cent of patients who had roentgenographs of the chest. As in psittacosis, the tetracyclines are of value in treatment.

In conclusion, all domestic and wild animals must be looked upon as potential reservoirs of virus or rickettsial infection which may be transmitted to man.

A Chronology of Cataract Surgery

An interesting history of one of the world's oldest surgical procedures.

THE HISTORY of cataract surgery goes back nearly 3,000 years to the ancient Code of Hammurabi. This was not a medical treatise, but a code of common laws. In this document, it was stated that if the surgery was successful, the surgeon should be paid with pieces of silver. However, if the operation failed, the surgeon was to have his fingers cut off. There was no mention made of the operative procedure as it was then known, since this information was passed by word of mouth only.

The next mention of the cataract operation is found in the writings of a great surgeon of India, Susruta, about 1000 B.C. It was he who first described the couching operation. This is the earliest known recorded description of the technique for the couching procedure. It was not until 320 B.C. when a Greek, Herophilus, became the first to remove an opaque lens from a living eye.

One of the earliest attempts at the definition of a cataract was made by Celsus in 30 A.D. He described a cataract as a suffusion or a slime which obstructed the pupil by "falling down" from above. It was also he who first described in considerable detail the technique of the couching operation. This procedure consists of penetrating the eye lateral to the cornea and just outside the corneoscleral junction with a sharp needle. The needle is then passed through the anterior chamber until the tip rests on the anterior capsule of the cataractous lens. The lens is then tipped backward and nasally, and is gradually dislocated until it falls downward behind the iris and comes to rest in the inferior portion of the vitreous. Partial vision is immediately restored to the eye. This however, may be of only a short duration because of the high incidence of postoperative infection and the frequent occurrence of severe irritative reactions in the eye resulting from the presence of the lens in the vitreous cavity.

Celsus was one of the earliest operators to recommend preoperative preparation prior to the cataract operation. This consisted simply of a

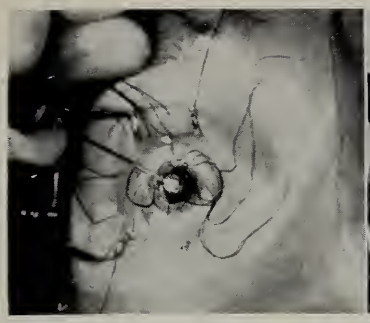

Fig. 5 *(left)*. Erisophake tip in place to grasp anterior lens capsule.

ROBERT R. COOPER, M.D.
Minneapolis, Minnesota

Presented as an inaugural thesis before the Minneapolis Academy of Medicine, November 18, 1957.

sparse diet, followed by three days of drinking water only and taking nothing by mouth the day prior to surgery.

The anatomist, Galen, who lived from 130 to 201 A.D., described a cataract as a concretion in the aqueous which could be displaced from in front of the pupil without causing damage to the lens. He considered this as a disease primarily of the brain and central nervous system, causing the opaque material to settle down in front of the lens, thus obscuring the vision.

The Arabian surgeon, Ammar (996 to 1020 A.D.), was the first to remove a cataract by the suction technique. By his method, an incision was made into the eye with a sharp instrument and a small glass tube inserted through the anterior chamber until it came into contact with the lens. An assistant sucked on one end of the tube while the operator maneuvered the other end until the cataract was seen to enter the tip of the tube. The instrument was then withdrawn and with it the cataract was removed. It is mentioned that the operator must be very skillful in this technique lest the entire contents of the eye be sucked out.

The concept of the morbid humor persisted from ancient time through the middle ages until 1705, when Michael Brisseau discovered that a cataract was actually a clouding of the lens itself.

In 1707, Charles St. Yves removed a lens which had been dislocated into the anterior chamber. This was the first recorded incident where a cataract had been removed en masse from an eye.

In 1745, the first deliberate cataract extraction was done by Daviel. From his procedure has evolved our present-day methods of cataract extraction. His technique was as follows: a keratome incision was made inferiorally in the cornea. This incision was enlarged with scissors, encompassing approximately 180 degrees of the corneal circumference. The corneal flap was elevated, and the anterior lens capsule was incised with a sharp needle. The lens material was then removed with a spatula.

Corneal incisions were made in the inferior portion of the cornea until 1784, at which time Pannard first made the incision in the upper portion of the cornea. This permitted better protection of the wound postoperatively and decreased the possibility of iris prolapse.

In the eighteenth century, a London surgeon, Percival Pott, invented the discission method of cataract extraction. This consisted of opening the capsule of the lens, permitting the aqueous to permeate the lens substance. This was followed by absorption of the soft lens material. His operation was the forerunner of our modern extracapsular technique of cataract extraction.

The iridectomy was first done as a preliminary procedure prior to the cataract extraction by Moore in 1864. This was done at intervals of several days to several months before the second stage where the lens was removed. The preliminary iridectomy served two purposes, the first to prevent iris prolapse at the time of the cataract extraction, and the second to determine the tolerance of the patient for ocular surgery in general. A combined cataract extraction, which consists of the iridectomy and removal of the lens as a one-step procedure, was first done by Von Graefe. Prior to 1867, the cornea was allowed to heal without any attempt at close approximation of the corneal incision. However, in that year, Williams was the first to use a corneoscleral suture to close the operative wound.

It was not until the early part of the twentieth century that the intracapsular cataract technique was established as an accepted procedure. In 1910, Colonel Henry Smith, while working in India, described a procedure for the removal of the lens *in toto* which has been known as the "Smith-Indian" operation. This consisted of a preliminary corneoscleral incision over the upper half of the cornea. Pressure was then exerted inferiorly, pushing backward against the vitreous until the inferior portion of the lens had been dislocated from its zonular attachments. By further pressure and manipulation from below, the inferior border of the lens was made to tip forward and was then delivered through the corneal incision by continued pressure through the inferior portion of the cornea with a muscle hook. As might be expected, this technique frequently led to the loss of a considerable amount of vitreous from the eye; however, this operation was widely accepted throughout the world for many years thereafter.

The actual grasping of the lens capsule as an aid in removal of the lens from the eye was first advocated in 1902 by Stoever, who devised a small suction-tipped instrument that we now call the erisophake. By the use of this instrument, the lens could be delivered through a combination of traction on the anterior lens capsule and pressure through the cornea with a blunt instrument. Since less pressure was necessary using this technique, there was consequently less chance of loss of vitreous during the extraction. It was shortly after Stoever's introduction of the erisophake that many forceps were devised to grasp the lens capsule.

In the first half of the twentieth century, there have been many notable contributions to the operation of cataract extraction not only in the development and refinement of the surgical technique, but in the fields of anesthesia, preoperative and postoperative management, and in the prevention of postoperative infection. Prior to 1919, anesthesia was obtained primarily through the use of systemic medication and topical drugs used directly on the anterior surface of the eyeball. Akinesis of the orbicularis muscle was first described in 1919, and in 1920 Van Lint introduced his technique of injection of procaine subcutaneously above and below the eye to block the terminal twigs of the facial nerve supplying the orbicularis muscle. In 1929, O'Brien described his method of blocking the facial nerve as it passes in front of the ear through the parotid gland by the direct injection of procaine into this area. It was not until 1930 that the retrobulbar block was introduced. This injection blocks the ciliary ganglion in the muscle cone and thereby produces complete anesthesia of the eyeball and its contents. These anesthesia procedures have enabled us to operate successfully on cataract patients without the added risks of general anesthesia.

The management of cataract patients preoperatively and postoperatively has improved through the years in much the same fashion as that with other types of surgery. The advent of the various antinauseants and the availability of a number of drugs to allay apprehension has permitted the surgeon to operate in many cases, where it otherwise would have been deemed inadvisable.

The use of the sulfonamide and antibiotic drugs has reduced the incidence of postoperative infection, which, in the case of a cataract operation,

almost invariably leads to loss of the eye or at least the loss of any usable vision.

It is evident that the evolution of cataract surgery, which began over 1000 years before the advent of Christianity, has been a long and tedious process. There has naturally been more progress made in the past fifty years than in all the time before. However, as is the case with many surgical procedures done today, a great many of our modern concepts are based on the work of men of foresight and imagination who lived, in some cases, as many as 3,000 years ago.

Discussion

Dr. W. J. Bushard: I would like to compliment Dr. Cooper on a very interesting paper. It is evident that real progress in successful cataract extraction was made following the advent of good anesthesia, particularly the use of local anesthesia introduced in approximately 1919. Dr. Cooper has reminded us the length of time, some 3000 years, needed to develop a technique quite safe. Indeed, the next important advance was the availability of good suture material to close the eye properly following the removal of the cataractous lens, making this procedure quite safe and highly successful in an otherwise normal eye.

Dr. Richard C. Horns: Probably the most important recent development in cataract surgery is improved wound closure. This improved wound closure is brought about by the use of radial sutures which suture the corneal wound edge to edge. It is possible to suture these corneal wounds edge to edge because of the development of extremely sharp hand honed cutting needles with very fine silk and very fine chromic catgut suture material. The other thing which helps in putting in these sutures is magnification of the operative field by means of a binocular loupe.

The development of the intraocular cataract lens makes it possible for a patient with a unilateral cataract to use both eyes together following cataract surgery. The best known intraocular lenses are the Ridley lens and the Strompelli lens. I feel that these intraocular lenses are still experimental and that eyes have been lost because of them. They cannot be recommended for regular use at this time.

Dr. Karl E. Sandt: In the past twenty-five years, we have seen the evolution from keeping a patient practically in a straight jacket to being up after surgery almost on the same day. I think this has been one of the greatest steps forward, as the patients no longer need fear confinement and postsurgical care.

Many men bandage only one eye, and sand bags, and other restraints are rarely used. The improvement of retrobulbar and lid anesthesia has facilitated the extractions immeasurably, and with the use of scleral-corneal sutures we can feel relatively free to allow the patient many privileges.

Also, we have been able to do surgery on people in their eighties and nineties and not have to feel required to keep them in bed. Their ambulation has apparently caused no difficulty in the healing of the wound and has certainly made it easier for the old folks.

WEIGHT REDUCTION AND DIET

Caloric overnutrition may be classified as the predominant American nutritional disease, and dietetic measures are of the greatest importance in the treatment of this disease.

Many diets have been proposed to bring about the correction of obesity. A diet consisting of bananas and skim milk was proposed by Harrop[1] in 1934. This diet included 44 gm. of protein, 4 gm. of fat and 182 gm. of carbohydrate, and it provided 940 calories per day. It was deficient in many of the vitamins and minerals that are considered to be essential.

More recently, Pennington[2] used a diet that was high in protein and fat and low in carbohydrate. The diet called for three parts of lean to one part of fat in meat, and calories theoretically were unrestricted. The program emphasized a definite routine for sleeping, eating and exercise.

Dole and associates,[3] in 1954, suggested treating obesity with a low-protein, "calorically unrestricted" diet, which became known popularly as the "Rockefeller diet." The amount of protein was limited to 35 gm. per day, but the diet provided a surplus of carbohydrate and fat. The authors stressed that the details of routine were important, including scheduling of meals, restriction in choice of food and regulation of activities. They found that the majority of patients soon returned to their previous ways of eating; three to twelve months after dismissal, 52 per cent of them had regained to their original weights.

The so-called "Rockefeller formula diet" also had its origin with Dole's group.[4] This 900-calorie diet contained approximately 21 gm. of protein, and it was extremely inadequate in iron as well as protein. The authors emphasized that the only advantages of this formula diet were its simplicity and inflexibility, and that the diet dealt only with the initial weight-losing phase in the total management of the obese patient.

Man cannot exist in defiance of the law of conservation of energy. Any diet designed to bring about loss of weight must provide fewer calories than the obese person requires to meet the needs of his body for energy. The so-called "calorically unrestricted" diet of Pennington actually may not have been unrestricted in that some of the patients following the diet probably did not eat all of the fat called for in the diet. After several days of eating large quantities of meat, they also may have found a lessened desire for such large amounts of meat and automatically may have reduced their caloric intake. Those patients following the low-protein, calorically unrestricted diet of Dole's group may well have experienced the anorexia of a deficiency in amino acids after using the diet for a time, and accordingly may have reduced their caloric intake.

All diets deficient in calories should be designed so that they are adequate in all aspects but calories. The recommended dietary allowances proposed by the Food and Nutrition Board of the National Research Council should be met for protein, vitamins and minerals. One may be reasonably sure that this has been done when the daily diet includes at least one serving of a leafy, green or yellow vegetable, at least one serving of a food high in ascorbic acid, two average servings of meat, fish, fowl or a substitute, one egg and 1 pint of milk. As a therapeutic measure, the patient may be advised to take a vitamin supplement.

The caloric content of the diet is lowered by decreasing the quantities of foods containing large amounts of carbohydrate and fat. Sugar and sugar-sweetened foods are used sparingly, if at all. Some low-calorie diets contain little fat other than that in meat, fish or fowl and eggs. Limited use of butter or other fats and oils is allowed, and skim milk is used rather than whole milk.

The low-calorie diet should be planned so that the patient will learn proper eating habits. Then, when he has reduced his weight to the desired level, he will know how to select and follow a nutritionally adequate diet that will maintain the ideal weight. The low-calorie diet should give him a basic pattern of eating that can be followed for the rest of his life. For that reason, a low-calorie diet comprising foods commonly available and conforming to the customs of the patient is to be

preferred over one that necessitates odd foods or odd times for eating.

POLICE TRAINING

Police training is a multi-ordinal term meaning many things to many people. To the officer of a large metropolitan department it may mean six years of college supplemented by pre-service recruit training, annual in-service refresher courses and specialized courses within the department. To the rural constable or suburban patrolman it may mean "riding" with an older officer for two months supplemented by occasional "chats" with the Chief.

The enforcement of laws and the regulation of human behavior is a stimulating and rewarding task. However, it is, at best, highly complex and demanding of the highest levels of judgment and intelligence. To excel the officer must be proficient in many skills. To be inferior or mediocre requires only daily periods of semi-consciousness preceded and followed by the punching of a time clock.

The "thief catchers" and the door shakers have gone the way of the "old lamp lighter." Their modern counterparts in municipal police departments have become buried under a mountain of mechanical gadgets for measuring, and recording everything under the sun—and many things under the skin. Radar speed measuring devices, traffic signals, polygraphs, alcometers and the like are common even in the smaller departments. Thus, the modern police officer is a sometimes engineer, electronics gadgeteer, chemist and quasi-psychologist. The trend in modern police work is away from rather than towards greater specialization, especially in the smaller departments. The suburban officer must be capable of operating all of the various devices within the department. In addition he must be skilled in the more traditional duties of first aid, photography, evidence collection, interviewing and interrogation, marriage counseling, foot and auto patrol, public relations and a host of other subjects.

It is sheer folly to clothe a person in a uniform, provide him with a badge and gun, and then proclaim to the world that he is a policeman. It is no less ridiculous than it would be to provide a man with a stethoscope, white coat and prescription pad and label him as doctor. The garb and tools of the profession must be reserved for those who exhibit a deep interest, understanding and ability for the disciplines of that profession.

Police training traditionally is classified into three major areas or types. First there is pre-service training which includes academic training received at an accredited college or university and may range from two to six years. The two-year program refers to the junior college training courses found primarily in California.

The second type of training and that which is found mostly in the larger cities is recruit training. Recruit training consists of fulltime class and field work given to probationary patrolmen immediately following appointment to a department. Such courses vary in length from a few days to two or three months and are geared to local needs. In a few sections of the country, area or county schools have been established to provide recruit training for a group of men from several small and medium sized departments.

The third type of training and that which is most common among the majority of communities is In-service training obtained either locally or away from the community. Specialized training in traffic law enforcement, delinquency control, laboratory and identification techniques and lie detection comprise the major areas for specialized training. Any training received by an officer after he has been on a department for a period of time would be considered as in-service. The classification of training is made then not on the basis of course material, but rather on the basis of length of service (or even lack of service) of the officer.

The greatest training challenge lies in the task of providing recruit and in-service training for the small and medium sized police departments. A department of less than 200 men is hard pressed

to provide an adequate recruit training program in view of the fact that appointments would be made in small numbers, perhaps never exceeding ten at any one time. Thus, the task of providing a uniform training program for all new recruits is beyond the ability of most departments and virtually impossible for the smaller departments.

Several workable solutions to the problem of training have emerged in the past few years. The first solution and perhaps the oldest is that of county-wide or area-wide schools designed to provide basic knowledge in those areas not strictly controlled by individual departmental policy. These area schools are operational in many sections of the country. The police schools of the Law-Medicine Center in Cleveland are somewhat unique in that they are operated by a private university (Western Reserve University) working in cooperation with a governmental office (Cuyahoga County Coroner's Office) and sponsored financially by the county commissioners. The Suburban Police School is a 170-hour course given during a calendar month. Offered primarily for the fifty-six municipal police departments in suburban Cuyahoga County, 338 students have successfully completed the first twelve sessions. Presently four sessions are offered in each calendar year, two being designated as advanced courses and two being designated as recruit courses. They both contain the same subjects, but the emphasis given to the various subjects changes to better meet the needs of each class according to their experience. In addition to the departments within the county, fourteen agencies from outside the county have sent men through the Suburban Police School.

The curriculum of a basic police training course which is offered on an area-wide basis is by necessity restricted to those subjects not in conflict with local ordinances or departmental policy. This restriction should not work any hardship on the planners of such courses since there is a vast number of subjects remaining to be covered. Major consideration must be given to state criminal statutes, court procedures, evidence rules, first aid, firearms practice, self-defense, public relations, criminal investigative procedures, psychology, interrogation techniques, traffic law enforcement, and a variety of other subjects. Every officer must be fully familiarized with the functions and duties of the other agencies with which he must work in his day to day job. These include the fields of the prosecutor, the courts, the probation officers, the juvenile officers and courts, the prisons and the parole officers. The team concept in the administration of criminal justice bears constant emphasis, for each of us tends to become provincial in our thinking and tends to resent those "outsiders" who also take an interest in the offender.

A second major solution to training for smaller departments has recently developed in New York state. Recent passage of the Municipal Police Training Council Act has provided the basic structure and organization for a state-wide program. The philosophy behind this act is sound and logical and it is surprising that similar legislation has not developed sooner. Police power in this country traditionally has been vested in the states from the time of the writing of the federal Constitution. The delegation of this police power to municipal law enforcement agencies likewise has been traditional. However, in all but a few states, the delegation has been complete with the state retaining control only in those areas where state civil service has dictated employment qualifications. In most other phases, local governing bodies have been given a free hand in the selection, training and direction of their law enforcement officers. In view of the fact that the great body of laws to be enforced are state statutes, central control on the state level does not appear illogical or unreasonable, especially where the communities of less than 10,000 population are concerned.

The New York legislation calls for the creation of a council which will establish training programs throughout the state where needed. When the program becomes established, basic recruit training will be mandatory. No police officer will receive a permanent appointment until he has successfully completed the required training course. This forward step has been a long time coming and should be welcomed as a major break-through in the search for professional police service.

The concept that basic training for law enforcement officers is a luxury which a community can afford only occasionally is totally false. No department is ever so shorthanded that it cannot defer using a man for a month while he is being trained.

THE HEALTH SIGNIFICANCE OF THE ENVIRONMENT

The relationship between factors of the environment and human health has been suspected for several centuries and well recognized for the past few generations. Even before the causative agents of specific diseases were known, it was found that the application of sanitary measures could have a profound effect on modifying the extent of outbreaks and epidemics. Scientific methods of control have replaced the early "shotgun" measures, with dramatic reductions in many of the diseases that once were common. Water-borne and milk-borne diseases have been reduced almost to insignificance in Minnesota and most of the United States through programs of sanitation in water supply and milk production and processing. Insect-borne diseases have also yielded to programs aimed at environmental control.

Environmental sanitation has been defined by the World Health Organization as "the control of all of those factors in man's environment which exercise or may exercise a deleterious effect on his physical development, health and survival." This is a much broader definition than that which may be in the minds of many people who regard sanitation as something related to water, sewage, and possibly garbage and nuisances. In many underdeveloped areas of the world, water supply and excreta disposal, while important, may be secondary in importance to insect problems.

Minnesota is fortunate in the fact that many of the environmental hazards that exist in much of the world, and even in other parts of the United States, are not present here. Environmental sanitation programs, and even total health programs, in many countries are devoted almost entirely to combatting such diseases as cholera, malaria, yellow fever, bilharziasis, African sleeping sickness, and others that are unknown in this area. (A program for reducing infant mortality, for instance, is of little value if the lives saved at this point are to be sacrificed to disease within a short time.) Minnesota is free of many of the parasitic and insect-borne diseases that occur or have occurred in some of the southern and coastal states. Climate plays a part in limiting the spread of these diseases but general living conditions are also a factor.

It might appear that under the circumstances there is little remaining to be done in the field of sanitation in Minnesota, but this is not the case. Even though a resident or visitor can safely drink water from most of the nearly 600 public water supplies in the state, constant vigilance is required to keep these supplies safe. Many private and semi-public supplies are unsafe and the only reason they have not caused major outbreaks is that the essential causative agent is lacking. Even so there is ample evidence that many cases of intestinal illness are caused by contaminated drinking water. The growth of population and industry challenges the best efforts in control of water pollution and will continue to do so. Many industries have processes that release toxic substances to the environment that need study and control. Air pollution and ionizing radiation are hazards only recently recognized by the public. The control of food service to prevent poisoning and disease requires constant and increased attention. Greatly increased activity in this area is highly essential. Lastly, the water and sewage problems of "suburbia" present the greatest sanitation challenge, not only in Minnesota but throughout the United States.

Several of the sanitation problems in Minnesota will be discussed in more detail in coming months.

F. L. Woodward, *Director*
Division of Environmental Sanitation
Minnesota Department of Health

SOCIAL ASPECTS OF AGING

One of the outstanding facts of our time is that the average length of life in the United States has gone up to around seventy-five years for white women and about seventy years for white men (slightly less for colored people). Furthermore, there is a greater likelihood for people to be physically healthy and vigorous in their later years than used to be true. Especially women, who in former years could be considered ready for the rocking chair or the grave when they finished rearing their children, today can usually look forward to twenty years of physical vigor as they reach the age of sixty.

But these biological improvements do not necessarily make for social happiness. In one sense, certain recent social changes have created new problems for elderly people, although these same social changes *could* be regarded as offering new opportunities if elderly people could learn how to take advantage of them.

In the first place, young people are less in-

clined to provide a home for their elderly parents than was true in former years. The greater mobility of young folks, the increase in apartment living with less space for "extra" people, the lesser need for help from the old folks, and the increased desire for independence on the part of the young, all make it less likely that an elderly person can count on living with his children.

Secondly, there is more likely to be enforced leisure in the later years. With various pension plans now in force, and a higher salary standard which makes employers less willing to retain workers when they begin to slow down, compulsory retirement at the age of sixty-five is rapidly becoming almost universal for employees. The situation for women has changed even more drastically. Today the average woman bears her last child at the age of twenty-six years, and when she has reached the early forties, she is "retired" from the main life occupation of child rearing. She still has to maintain a household for her husband and perhaps an adult child or two, but household care without small children is much simplified. So the physically vigorous woman of forty-five years, like the man at sixty-five years, has to seek a new major life role. Society does not automatically provide a new major life role for the "retired" because there is a heritage from the past that "retired" persons were so tired out that they were likely to want only to sit in peace or be restricted to an invalid's bed.

Thirdly, the prestige of age has declined. In past centuries, age was supposed to be associated with wisdom, but today the pace and complexity of events attributes wisdom only to the expert. Also, the elderly person was relatively rare in the past; today the percentage of those over sixty-five years in the population has climbed to almost 1 in 6. The inflation in numbers has seemingly reduced the popularly evaluated worth of the aged person.

These and allied social changes have created a kind of "looseness" in the position of the elderly in our society. They are less likely to have a job, a home (with other people in it), a major life role, honor or recognition than was the case for their counterparts up to a generation ago. Many of the old supports for the elderly have disappeared, and new substitutes are only beginning to develop. During the transition, the elderly are naturally somewhat "lost."

But our society is rapidly developing new institutions and new facilities to restore the elderly to a valued position in the social structure. Social security and retirement systems are providing economic security. Careful thought and guided action are being applied to the housing needs of the elderly. "Golden Age Clubs" and similar organizations are developing to provide for the sociable and recreational needs of the elderly. Some preliminary suggestions of participation of the elderly in politics, if considerably developed, might lead to a higher social status for those who are active. In the case of women especially, whole "careers" are being carved out through work in a great variety of voluntary organizations, in which contributions are made to the community as well as to one's own sense of satisfaction.

These leads are promising, although they have to be greatly expanded and somewhat modified in character to serve the large and growing numbers of the retired. As far as the position of the elderly in American society is concerned, we are truly in the age of transition. But promising developments are taking place, and, best of all, the American people are becoming aware of the problems of aging, so that at least some of the difficulties of the elderly in modern society are on the road to being solved.

Professor of Sociology
University of Minnesota

MEDICAL SCHOOL NEEDS

In answer to a recent questionnaire submitted by the American Association of Medical Colleges, the deans of seventy-eight fully developed four-year United States medical schools reported that a total of $1,230,774,000 has been spent since 1948 on the construction of teaching, research and hospital facilities. Of this total, $693,774,000 was spent for facilities on which no federal funds were expended and $537,000,000 on facilities which included $133,500,000 in federal funds in their total construction budgets.

The seventy-eight deans also reported a need for approximately $293,000,000 for new construction and/or renovation of teaching facilities. This does not include their estimates of construction needs for research facilities or hospitals.

If funds were available, sixteen schools indicated that they could start immediate construction on facilities costing $41,500,000; thirty-six schools could begin construction estimated at $184,500,000 by 1960; and by 1961 an additional fourteen

schools could begin construction estimated at $48,000,000. Of the remaining schools, seven indicated no immediate needs, and five could use $19,000,000 between 1962 and 1966 for teaching facilities.

The deans estimated that 850 additional freshman medical students could be accepted by 1965 if funds were made available soon for this construction and renovation program.

Academic Deficits

Budgeted academic vacancies in the United States medical schools have shown an alarming increase in recent years. For instance, budgeted vacancies in 1957-58 were almost twice the number reported for 1956-57: 331 as contrasted with 619.

More startling, however, were the results of a sample questionnaire relative to the number of additional faculty needed, over and above vacant budgeted positions, to teach medicine as it should be taught today. Twenty schools (twelve tax-supported and eight private) reported an average need of fifty additional faculty members—forty-three junior and senior faculty members in traditional departments and six or seven faculty members in the so-called "new disciplines"; that is, physical medicine and rehabilitation, biophysics, biostatistics, psychology, et cetera, as well as eighty additional supporting personnel per school, such as the administrators, clerks, and technicians. Converted to dollars on the basis of prevailing average salaries, approximately $500,000 per school would be needed to hire these people. This is to be compared with a dollar need of $250,000 per school reported in 1953 *(Journal of Medical Education,* February, 1953, by Dr. Ward Darley) to correct academic deficits. Considering the change in demands on schools and problems resulting from increased research, et cetera, this jump to $500,000 per school may be a reasonable estimate.

Tuition Fees Increasing

Since 1939, the average annual tuition fee for medical schools in the United States has increased 114 per cent. Thirty-two per cent of the increase occurred between the years 1950 and 1956. During this same six-year period, the average family income increased 30 per cent, and the cost-of-living index increased by 16.9 per cent.

Early reports from a few medical schools indicated that some schools will raise tuition fees again this year.

MEDICAL SCHOOL APPLICATIONS

The total number of medical school applicants seems to be decreasing in the face of increasing enrolments and increasing graduates from colleges:

Year	*Total Students Enrolled in Colleges*	*Total Number Graduating*	*Total Number Medical-School Applicants*	*Number Medical-School Applicants Represented as Percentage of College Graduates*
1950	2,296,592	433,734	22,279	5.1
1957	3,068,417	340,347	15,791	4.6
1958	3,258,556	365,748	15,172	4.1

The percentage of students entering medical schools with an average grade of A has been decreasing:

College-Grade Average First-Year Medical Students	*1950-1951 (Per Cent)*	*1957-1958 (Per Cent)*
3.6-4.0 (A)	40	18
2.6-3.5 (B)	43	66
1.0-2.5 (C)	17	16

There are also some disturbing trends in the MCAT scores as reported by the research division in the applicant study appearing in the April issue of the *Journal of Medical Education,* ". . . scores of all first-time applicants for each of the years 1952-57, clearly show that a decline in quantitative aptitude and scientific skills as measured by MCAT has occurred, accompanied by a rise in verbal aptitude." However, preliminary studies of the 1958-59 freshman class showed significant increases in both quantitative and science scores, and the average scores for applicants to the 1959-60 class are showing similar trends.

The percentage of students withdrawing during their freshman year in medical schools increased from 5.5 per cent in 1954 to 1955 to 7.8 per cent in 1957 to 1958. Actually, fewer students were available for the second-year class from the 1957 to 1958 class than from the 1956 to 1957 class.

Year	*Total Enrolled in First-Year Class*	*Number Withdrawing*	*Percentage Withdrawing*	*Students Available for Second-Year Class*
1954-55	7,576	418	5.5	7,158
1955-56	7,686	480	6.2	7,206
1956-57	8,014	544	6.8	7,470
1957-58	8,030	629	7.8	7,401

The number of students withdrawing, both in poor and in good standing, increased steadily since 1954:

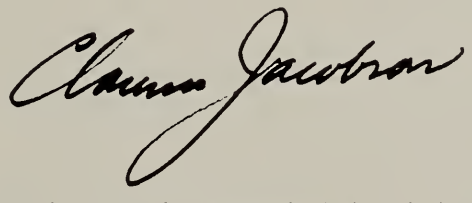
Year	*Poor Standing*		*Good Standing*	
	Number	*Per Cent*	*Number*	*Per Cent*
1954-55	257	3.4	161	2.1
1955-56	324	4.2	156	2.0
1956-57	368	4.6	176	2.2
1957-58	448	5.6	181	2.3

Association of American Medical College

President's Letter

PROFESSIONAL RELATIONS

Members of the medical profession continue to be critical of themselves as individuals and of one another as to what constitutes good practice and proper conduct. Standards are constantly reappraised and implemented to render a high quality of medical service in the treatment and prevention of disease.



The demand for proper distribution of this service to everyone in need, regardless of ability to pay, has assumed challenging proportions in our present day economic life. Meeting the demands of groups and individuals who are motivated by philosophies alien to tried and time-proven processes, continues to demand united planning and action by organized medicine and their allied agencies.

These times of relative affluence have served to cloud the urgent necessity of the doctor to examine the active forces working to enroll the profession in the service of the state. These alien forces came into being because we have not heeded what the public demanded of us, namely, providing good medical and hospital service within the means of the average income group. The doctors and hospitals came forth with what appeared to be an ideal solution when they instituted Blue Shield as the doctors' plan and Blue Cross as the hospital plan. The early years of these agencies satisfied the needs of the public. As time went on, complexities increased because the rapid advances of medical knowledge demanded expanded facilities for better diagnosis and treatment. The rapid growth of these two agencies together with improved administrative methods kept pace for a time, but soon increases in premiums became necessary. In many areas, Blue Shield was able to meet these demands with modest increases and at the same time offer increased coverage. Blue Cross had problems of increased utilization, higher hospital costs due to increased wages of hospital personnel and expanded diagnostic facilities. Both plans are now in competition with attractive commercial policies offered by large insurance companies who originally had little or no interest in prepayment service plans. This situation in recent years has served to change the original relationship between Blue Cross, Blue Shield and the public it serves. Too often health and welfare issues, when brought to the bargaining table, are a matter of dollars and cents and not necessarily one of service required or provided.

The magnitude of our health problems can be comprehended when we observe what the federal government spends and threatens to spend on welfare in addition to our growing prepayment movement. More than 20 billion dollars is asked for the

coming fiscal year. This item is second only to what is needed for the defense budget. The proposed Forand Bill, with its growing potential, will serve to dilute the other services. This threat has given some of our congressmen pause. In the Eighth District doctors have been asked their opinion of this measure by one of our representatives.

This pause for reflection we hope is sincere, for it affords us opportunity to re-examine our measures to avoid governmental intervention in the practice of medicine. The immediate future may provide our last opportunity. The answer broad enough to meet the objection of oversimplification is obvious. Better professional relations involving organized medicine, Blue Cross and Blue Shield have been responsible for improved co-ordination, resulting in a type of service which maintains confidence of the public in the voluntary system in the majority of states. We must realize that Blue Shield and Blue Cross cannot long exist without the support of the medical profession. Nor can we hope to practice as an independent medical profession without these agencies. Better relationship demands improved communications between our state and county organizations and their components, Blue Cross and Blue Shield and the Hospital Association. We cannot afford prolonged dissension when the fore-mentioned challenges face us. The voluntary system can prevail when these agencies and the medical profession assume their responsibilities with wisdom and maturity. Existing differences between these two great agencies could in all probability have been avoided, to the benefit of all concerned. We will continue to learn much from one another. Differences of opinion can serve to strengthen us, when resolved by understanding and by confining our attention to the issues involved. This we are capable of doing in a statesmanlike manner and by so doing we can work together to merit the growing support of a sound voluntary system of prepaid medical care.

Civil Defense News

Carl Waldron, M.D., D.D.S., *Chairman, Civil Defense and Disaster Committee, Minnesota State Medical Association*

M. D. Tyson, *Civil Defense Co-ordinator, Minnesota State Department of Health*

CIVIL DEFENSE SURVIVAL PLAN

To understand better the organizational pattern for the Civil Defense Health, Medical and Special Weapons Defense Service plan, a few items concerning out State government and certain basic assumptions should first be mentioned.

Throughout our Civil Defense planning, attempt was made to utilize, wherever possible, existing state departments to implement the several services organized under the Civil Defense Survival Plan. The Executive Officer of the State Board of Health, by executive order of the Governor, was designated State Chief of the Medical Service. However, in Minnesota, the state mental hospitals and allied institutions are under the supervision of the Division of Medical Services of the State Department of Public Welfare. This Division of Medical Services is headed by a medical director who supervises approximately ten thousand hospital beds outside the target areas. Accordingly, the director of this division was appointed State Chief of the Service's Medical Care Division.

Prior to writing the medical plan, several assumptions were made.

1. The first was that, as a general thing, each hospital in our state—subject to individual variation—had a capability to expand *within its community* to a capacity equal to ten times its normal licensed capacity.

2. The second assumption was that in the event of a Civil Defense Emergency, our problem might be mainly one of well evacuees or might mainly be one of casualty care, or it might be a combination of these two.

3. A third assumption made was that any medical installation could, without difficulty, care for non-casualty evacuees: however, the converse is not true. Thus, it was decided that the Service would have priority over the Welfare Service for the use of a community's facilities.

4. A fourth assumption made was that each hospital would have the capacity of collecting pints of whole blood each dav in an amount equal to its licensed bed capacity for a period of thirty to sixty days and probably much longer.

5. A fifth assumption made was that nursing homes and boarding care homes were not primarily a medical care responsibility but would be handled, except for urgent, necessary medical services, by the Welfare Service.

Within the State of Minnesota and the Northwest Wisconsin Disaster Region II (immediately to the east of our eastern border) there are approximately thirty thousand licensed hospital beds. Of these, ten thousand are within target areas and might not be available in the event of a Civil Defense emergency. As part of our Survival Plan, site-to-site relocation of these target city hospitals is planned, should time permit. Were this not possible, we would be left with twenty thousand beds outside the target areas, which, if expanded ten to one, would provide some two hundred thousand beds in the reception areas. Professional personnel to staff these institutions would have to come from target areas and could reasonably be expected to get out proportional to the number of casualties.

The Civil Defense Health, Medical and Special Weapons Defense Service plan provides that during a Civil Defense emergency:

1. It is the resopsibility of the Service to provide all emergency medical care and treatment of the general population and Civil Defense personnel, to provide emergency public health services to meet disaster conditions, and to provide preventive and remedial measures to minimize the effects of plant and animal biological warfare and chemical warfare.

2. All medical supplies, equipment and special medical vehicles are under the control of the Service.

3. Manpower needed in addition to that preassigned to the Service may be requisitioned from the Civil Defense Manpower Service.

4. All medical facilities in the county and municipality are under the control of the Service, and the Service has priority for the use of other public, semi-public and private structures in the state.

5. If there is time, target area hospitals' professional staff, auxiliary personnel, material and patients will be relocated out-state.

6. Emergency treatment stations will be established on the periphery of the target areas on the evacuation routes.

7. Non-target area hospitals will expand their facilities by ten times their licensed bed capacity.

8. Medical care and treatment will be provided for target area casualties, the local population and Civil Defense personnel at either an

TWO-BED HOSPITAL ROOM CHARGES VARY WIDELY THROUGHOUT THE UNITED STATES

Minneapolis ranks in eighth place among major cities over 100,000 population in the United States with respect to the average charge for a two-bed semi-private hospital room.

The average charge for a two-bed semi-private hospital room in cities of more than 100,000 population ranges from a low of $9.29 a day to a high of $27.80 a day, according to a report of the Health Insurance Institute. When the nationwide survey was extended to cities with populations of 25,000 or more, the variance was wider, with a low of $8.00 a day and a high of $32.00 a day.

The study was based on information supplied by the American Hospital Association from a survey of hospitals throughout the United States conducted early in 1959. The survey measured weighted average hospital room rates for cities of 25,000 or more population.

The survey disclosed that generally rates and charges were higher in the West, Northeast, and North-Central sections of the country and lower in the South.

There also is a considerable spread in the average hospital rate within larger cities, due to the existence of both large and small hospitals, of which some offer comprehensive services and others make available simpler services.

The difference in hospital rates and charges is reflected in most health insurance programs, whether it is a group plan or an individual policy.

"Provision of medical care in the United States historically has been local in character and the charges established by the providers of medical and hospital services therefore reflect not only the cost of living in the local community, but the range of services provided and the types of patients served," stated the Institute.

Rates By City

The average rate for a two-bed semi-private hospital room, which varies both between cities and within cities, is listed below for some of the nation's larger cities, in descending order of cost:

Oakland, $27.80; Los Angeles, $25.40; San Francisco, $25.22; Cleveland, $24.34; Boston, $24.04; Seattle, $23.50; New York City, $20.93; Minneapolis, $20.63; Detroit, $20.00; Washington, D. C., $19.80; Chicago, $19.77; Phoenix, $18.86; Milwaukee, $18.24; Indianapolis, $18.11; Baltimore, $16.94.

Omaha, $16.85; Pittsburgh, $16.85; Philadelphia, $16.48; St. Louis, $15.88; Denver, $15.66; Kansas City, Missouri, $15.29; Salt Lake City, $14.71; Dallas, $14.44; Louisville, $14.30; New Orleans, $14.28; Miami, $14.24; Memphis, $13.68; Atlanta, $13.06; Tulsa, $12.09; and Montgomery, $9.29.

Nearly 22 million persons, one out of every eight in the United States, were admitted to the nation's short-term general hospitals in 1958, according to statistics of the American Hospital Association.

NEED FOR MORE PHYSICIANS FOR A GROWING POPULATION CITED

"The need to produce 3,600 additional physicians a year by 1975 in order to keep pace with a growing population is a problem of such magnitude that it demands the immediate attention of all medical schools and all other groups concerned with medical education," the President of the Association of American Medical Colleges asserted at the opening session of the Seventieth Annual Meeting.

Doctor John McK. Mitchell, Dean of the University of Pennsylvania School of Medicine, referred to the findings and recommendations made by the Consultant Group on Medical Education of the United States Public Health Service, of which he is a member. Their report, "Physicians for a Growing America" has just been released.

In his talk, "The Medical Schools are the Keystone of Medical Progress," Doctor Mitchell warned that we are already falling short of maintaining the ratio of physicians to population that has existed in the United States since 1940, a level considered by the report to be a minimum satisfactory goal. Doctor Mitchell pointed out that the two stumbling blocks to obtaining an ample supply of well qualified students lay in the length and cost of medical education. Noting that ample scholarships are available nationwide to Ph.D. candidates in fields related to medicine, such as physics, chemistry, and biology, he revealed that there are no federal, local or private programs of scholarship aid for medical students comparable to those

for other graduate students. He believes, therefore, that it is up to the medical schools to raise funds for scholarship and loan funds from both private and governmental sources.

this responsibility and will continue to use all resources at their command to further reasonable solutions. He pointed out that the medical schools also can contribute to this effort by "helping con-

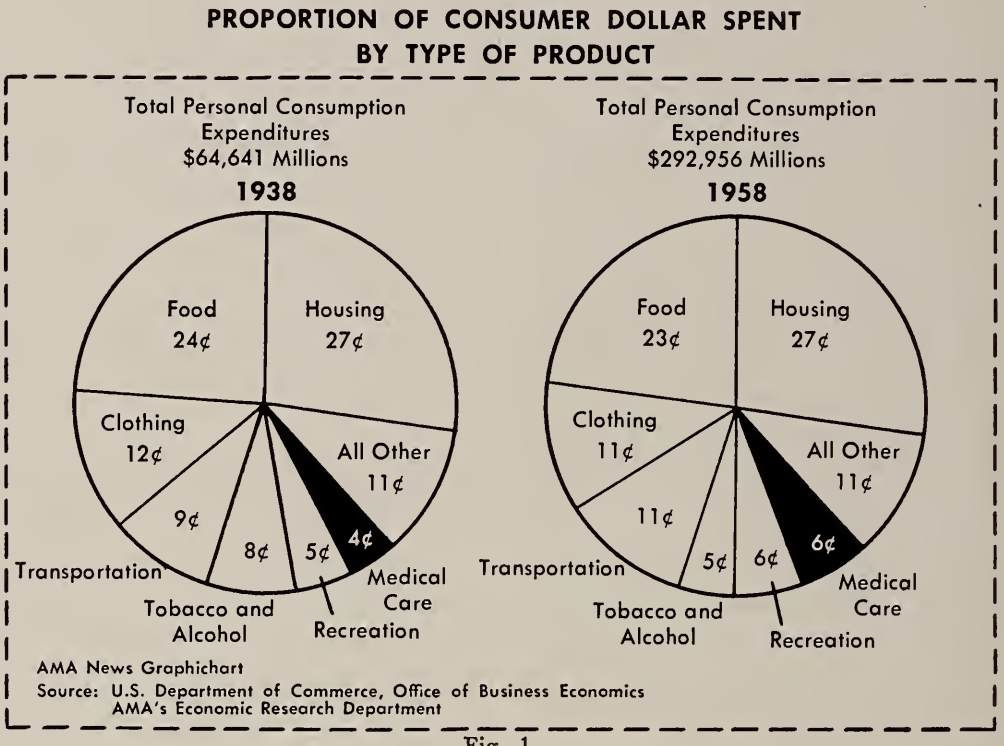

Fig. 1.

Doctor Mitchell said the report offered three solutions for meeting the medical manpower requirements: increased enrollment in existing schools, inauguration of new programs of basic medical science, and the establishment of new four-year medical schools. He emphasized that a major contribution must come from new four-year schools. However, he continued, if $325 million were available for new construction and renovation of teaching facilities, existing schools could increase their annual admissions by about 1,060 students. He urged that steps be taken to provide the necessary funds.

In a report to the medical educators, Dr. Leroy E. Burney, Surgeon General of the United States Public Health Service, said, "The problem of medical education will not be solved unless they are recognized and dealt with as matters of public policy by responsible leaders at all levels of government and in all sectors of national life."

Doctor Burney told his audience that the Public Health Service and the Department of Health, Education, and Welfare have taken their share of vince the American public that the need exists for a multi-million dollar expansion of existing schools and the establishment of twenty to twenty-four new two-year and four-year schools." The Surgeon General also based his statements on the new report of the Consultant Group on Medical Education.

The principal recommendation of the consultants, the Surgeon General said, was directed toward bringing about an increase in the number of physicians graduated annually from schools of medicine and osteopathy from the present 7,400 to some 11,000 by 1975.

DOCTORS GET SMALLER SHARE OF MEDICAL CARE DOLLAR

American physicians and dentists are getting a smaller share of the medical care dollar today than they did twenty years ago.

This fact has been revealed by the Economic Research Department of the American Medical Association, based on United States Department of Commerce data.

In 1938, physicians received 31 cents of the medical care dollar, but the physician's share in 1958 was 24 cents—or 22.6 per cent less than twenty years ago.

In addition to the amount which physicians and dentists received as their share of the medical cost dollar, 22 cents went for drugs in 1938, but the figure dropped 9.1 per cent in 1958 to 20 cents.

PROPORTION OF DOLLAR SPENT FOR MEDICAL CARE BY TYPE OF CARE

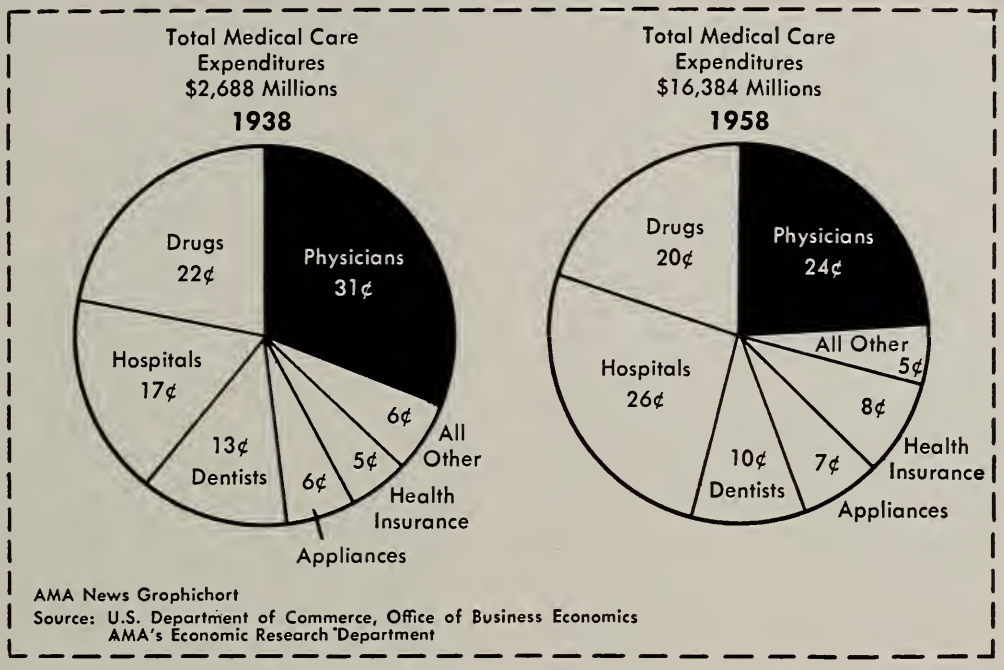

Fig. 2.

Dentists received 13 cents of the medical care dollar in 1938, but their share dropped 23.1 per cent to ten cents in 1958.

The breakdown of figures was based on a total of $16.4 billion spent for medical care in 1958—an average of $95 per person.

This represents 5.6 per cent of the $293 billion spent by Americans during the year for all goods and services.

The percentage of 1958 expenditures for medical care compares with 5.8 per cent for recreation and 5.3 per cent paid out for tobacco and alcoholic beverages.

Of total consumer expenditures for medical care in 1958, hospitals claimed $4.3 billion, physicians $3.9 billion, drugs $3.3 billion, dentists $1.7 billion, health insurance $1.4 billion, and ophthalmic products and orthopedic supplies $1.1 billion.

The remaining $769 million went for all "other medical costs," including osteopathic services, private duty nurses, chiropractors, chiropodists, and other miscellaneous curative and healing services.

Purchases of appliances took another 7 cents of the 1958 dollar, while items in the "all other" categories claimed the remaining 5 cents.

Items showing a proportionate increase include hospitals, which received 17 cents of the dollar in 1938 and 26 cents in 1958—a jump of 52.9 per cent. Hospitals attribute this rise to the expansion of hospital services and their greater utilization which has increased the number and variety of skilled personnel required.

More than 71 per cent of the United States population today is protected by some form of health insurance, compared with less than 10 per cent in 1938.

This means that in a large measure illness is not being paid for by income received in any particular day, week, month or year.

And while more Americans are budgeting more of their income for medical care, and more emphasis is being placed on planning against future illness, the physician is receiving a smaller portion of the total money spent for medical care.

PHYSICIAN COSTS SHOW INCREASE OVER FEES

Physician's fees have risen only 84 per cent during the past twenty years, while the cost of clerk's salaries has risen 203 per cent during the same two decades. Nurse's salaries have risen 177 per cent. Many other costs of medical practice have risen sharply in contrast to the rise in most physician's fees.

Since 1939, automobile insurance has risen 166 per cent; automobile repair, 94 per cent; gasoline, 80 per cent; motor oil, 57 per cent; and the cost of a new car, 130 per cent.

For the same period, the cost of office furniture rose 125 per cent; professional equipment, 93 per cent; rent, 60 per cent; telephone service, 56 per cent, and gas and electrical service, 11 per cent.

Costs of supplies and services have also risen substantially. Today, bath towels are 170 per cent above 1939 prices; bed sheets, 133 per cent higher; toilet tissue, 93 per cent; laundry soap, 87 per cent; toilet soap, 73 per cent; cleaning and pressing, 73 per cent; surgical dressings, 37 per cent and stationery, 135 per cent.

CIVIL DEFENSE

(Continued from Page 202)

ETS or an expanded hospital facility. Priority for all medical care is:

(a) Maintenance of health and production capability of non-casualty survivors.
(b) First aid and medical-surgical attention minimal (walking wounded) casualties to return them to productivity as soon as possible.
(c) Medical care to women of child-bearing age and children.
(d) Casualties that reach the medical channels.

9. Whole blood will be collected by each hospital each day in an amount of pints equal to its licensed bed capacity.

10. Public health nursing services will be provided.

11. Emergency environmental health measures will be established.

12. Plant and animal biological warfare and chemical warfare defense measures will be established.

13. Mobile personnel and equipment support will be provided as needed and within prevailing capabilities.

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

NIGHT CLUB MUSICIAN POSING AS PHYSICIAN SENTENCED FOR ILLEGAL POSSESSION OF NARCOTICS

On January 22, 1960, Robert A. Crea, thirty-one, 1490 Sargent Ave., St. Paul, was sentenced by the Hon. Leslie L. Anderson, Judge of the District Court of Hennepin County, to a term of not less than five years and not more than twenty years in the State Prison at Stillwater on a charge of illegally possessing narcotic drugs. Judge Anderson then suspended the sentence and placed the defendant on probation for the same period of time. Crea had previously entered a plea of guilty to the charge on December 15, 1959 before District Judge D. E. LaBelle who then referred the matter to the Hennepin County Probation Office for a pre-sentence investigation.

The defendant was arrested on December 7, 1959 after a number of complaints had been received from Minneapolis druggists that a man posing as a doctor had been telephoning their stores stating that he had issued a prescription for 40 tablets of dilaudid for a patient at a certain address, and that the prescription would be furnished at the time the drugs were delivered to the home of the patient. On December 7, 1959, Alan Lee Palmquist, sixteen, a delivery boy for the Lakeview Pharmacy, 3342 Hennepin Avenue, identified a photograph of a man who, earlier that day, had handed him a crude non-printed prescription made out in longhand for 40 tablets of dilaudid, at the time that delivery of the tablets had been made. The prescription bore the purported signature of a doctor of medicine. The photograph which Palmquist identified was that of the defendant.

Crea, who has no medical training and is a musician in a Hennepin Avenue night club, admitted that he had obtained dilaudid in a similar matter from more than ten Minneapolis pharmacies. At the time Crea was arrested a vial containing fifteen tablets of dilaudid was found in his shirt pocket, which made it possible for the charge of illegal possession of narcotics to be filed against him. Although the defendant has no prior conviction for a felony, he was convicted of a misdemeanor in Minneapolis Municipal Court on August 23, 1957. On that date Judge Dana Nicholson sentenced Crea to a ninety-day term in the Minneapolis Workhouse on a charge of possessing an implement for the use of a narcotic drug. However, Judge Nicholson suspended the sentence on condition that the defendant be of good behavior.

ARE FEWER MEDICAL STUDENTS WORKING?

It appears that fewer medical students were employed during the academic year 1957-58 than in the two immediately preceding years. The dean's office of thirty-nine United States medical schools recently reported that 27.4 per cent of the students were employed during 1957-58. This compares with 35 per cent who were employed in 1956-57, as reported in "Ecology of the Medical Student." Approximately 49 per cent of the students were earning part of their medical school costs in the school year 1955-56, according to a sample survey of forty-four schools conducted by the National Opinion Research Center.

Public Health

MEDICAL LABORATORY SURVEY IN MINNESOTA

Current considerations in medical laboratory work in Minnesota are for the development of a program in evaluation of chemistry procedures and technical consultation. This has grown out of the results of a survey of medical laboratories conducted in the state in 1957 and 1958. The survey results are reported in a paper entitled "Design for Development of Medical Laboratories: Personnel and Practices," by Ruth I. Heinemann, M.T. (ASCP), Henry Bauer, Ph.D., and Helen L. Knudsen, M.D., which appeared in *The Journal of Medical Technology* (Vol. 25, No. 3, 1959).* The survey was one of the activities of the Hospital Services Demonstration Program† of the Minnesota Department of Health. Earlier work supported by the W. K. Kellogg Foundation indicated the need for obtaining this base line of information from which needs could be determined for developing effective measures in providing better patient care in the state. Interest in medical laboratories in Minnesota shown by the Minnesota State Medical Association, Minnesota Hospital Association, Minnesota Society of Clinical Pathologists, Minnesota Society of Medical Technologists and others led to the development of the project supported by the W. K. Kellogg Foundation and that of the Hospital Services Demonstration Program.

The survey in 1957-58 was conducted through personal interview of medical laboratory personnel in all instances, and pathologists and hospital administrators when interest was indicated. The questionnaire form used in the interviews consisted of 182 questions of which 149 were coded and tabulated by International Business Machine equipment. A total of 181 of the 183 licensed hospitals were visited by two medical technologists (ASCP). In the tabulation of the results, thirty-six of the hospitals were excluded because they either did not have laboratory personnel or equipment, or they did not have the personnel to use the equipment that was in the laboratories. In addition, University Hospitals, Mayo Clinic, St. Mary's Hospital (Rochester) and Veterans Administration Hospital were excluded.

The results of the survey are reported under main topics on the basis of over-all summary analysis, personnel training level analysis and bed capacity group analysis. The bed capacities of the hospitals range from 6 beds to 565 beds. They are divided into five groups. Those in the first three groups (0 through 20 beds, 21 through 30 beds, 31 through 70 beds) are found in cities of population of 6,000 and less and are designated as rural hospitals. Those in the other two groups (71 through 130 beds, 131 beds and greater) are found to be in cities of population of more than 6,000 and are designated as urban hospitals. The personnel are divided into five groups of which three are designated generally as medical technologists (M.T.(ASCP)** with degrees, M.T. (ASCP) without degrees, and technical personnel who have had at least two years of college work but are not certified "M.T. (ASCP)"). The other two groups are designated generally as laboratory assistants (technical personnel who have had one year or less of training in which the academic and practical have been combined, and those who have had training on the job).

The major findings of the survey are summarized below on the basis of these analyses.

1. Three-fourths of the 145 laboratories surveyed are in rural hospitals.

2. Urban hospital laboratories employ two-thirds of all of the 614 technical personnel.

3. Approximately half of the personnel are medical technologists.

The main portion of this article is abstracted from the published report, "Design for Development of Medical Laboratories: Personnel and Practices," by Ruth I. Heinemann, M.T. (ASCP), Henry Bauer, Ph.D., Helen L. Knudsen, M.D., appearing in *The American Journal of Medical Technology*, 25:3, 145-165, 1959.

*Reprints are available upon request from the authors at the Minnesota Department of Health, University Campus, Minneapolis 14, Minnesota.

†The Hospital Services Demonstration Program was supported by research grant W-49 from the United States Public Health Service, National Institutes of Health, Division of Research Grants.

**M.T. (ASCP): Medical Technologist certified by the Registry of Medical Technologists of the American Society of Clinical Pathologists.

4. In urban laboratories most of the personnel are medical technologists. The medical supervision is given by pathologists. Technical supervision is given by medical technologists.

5. In rural hospital laboratories a large proportion of the personnel is laboratory assistants. There is almost no medical supervision. Technical supervision is given by laboratory assistants.

6. The mean and median salaries for technical personnel in urban hospitals are higher than those for technical personnel in rural hospitals. (The mean salaries in the urban groups are $297 and $346 respectively. Those in rural groups are $281, $272, and $287 respectively). The mean salaries for medical technologists are higher than those for laboratory assistants. (The mean salaries for medical technologist groups are $377, $356, and $331 respectively. Those for laboratory assistant groups are $262 and $278 respectively.)

7. Only medical technologists (ASCP) with baccalaureate degrees show a consistent increase of salary with increased experience. (A mean of $350 at less than one year of experience increasing to a mean of $406 at more than ten years of experience.)

8. Medical technologists have a greater mean experience (7½ years) than do laboratory assistants (5 years and 1 month).

9. Technical personnel, particularly those in rural laboratories, attend professional meetings to a limited extent.

10. The stated need for additional personnel is for twice as many medical technologists as laboratory assistants. Three times as many medical technologists are stated to be needed in urban laboratories as in rural.

11. Non-technical personnel assist with clerical and/or maintenance duties primarily in urban hospital laboratories.

12. There is a greater variety of technical procedures and equipment in urban hospital laboratories than in rural.

13. Two-thirds of the colorimetric instruments are pre-calibrated. Most of them are in rural laboratories. One-fourth of the colorimetric instruments have been calibrated each time a procedure is done.

14. Two thirds of the laboratories purchase all of their reagents ready for use. Almost all of the rural laboratories and a small number of the urban laboratories do this.

15. Quality control measures are used to a greater extent in urban hospital laboratories than in rural hospital laboratories. Solutions of standard concentration for instrument calibration and commercially prepared artificial serum are used in more hospital laboratories than are solutions of standard concentration for recovery measurement and pooled serum.

16. Almost all of the hospital laboratories expressed an interest in state-wide evaluation studies in all phases of medical technology and particularly in hematology, chemistry and blood banking.

The review of the survey findings resulted in proposing five programs for developing medical laboratory services in hospitals in Minnesota. Each was proposed with full realization that successful planning and implementation are dependent upon joint participation of the medical technologists, pathologists, other practicing physicians, hospital administrators and members of the staff of the Minnesota Department of Health. The programs are as follows:

1. The establishment of a laboratory which will serve as a central point from which evaluation studies may be conducted in several fields of medical technology.

2. The promulgation of consultation services in laboratory techniques and related matters in medical technology, particularly in rural areas.

3. The establishment of refresher training and specialized training courses to provide group instruction in areas of need indicated by evaluation studies and consultation.

4. The continuation of personnel recruitment programs with emphasis on supplying more medical technologists to rural areas dependent upon recognition of this need through increased salaries and variety of work.

5. The development of a uniform system of tabulating work load in hospital laboratories to facilitate interlaboratory comparison of work done.

The current considerations growing out of the survey for the development of an evaluation and technical consultation program for laboratories in Minnesota encompass the first two proposals. The need for this evaluation and technical consultation is emphasized by the findings that almost all of the laboratories are interested in evaluations, and that there is a small number of colorimetric instruments which are regularly calibrated as well as limited use of quality control measures in the hospital laboratories. This program has been duly considered and approved in principle by the Minnesota Commission on Patient Care, the Minnesota Society of Medical Technologists and the Minnesota Society of Clinical Pathologists.

Ruth I. Heinemann, M.T. (ASCP)

Medical Legal Opinion

● *The purpose of this section entitled Medical Legal Opinion is to publish news of recent litigation concerning medical practice as well as to cite past actions and opinions of the Court in medical legal matters as a means of refreshing our knowledge of such procedures.*

American Hospital Association

STATEMENT OF HOSPITAL—PHYSICIAN SPECIALIST RELATIONSHIPS

In Anesthesiology, Pathology, Physical Medicine, and Radiology

At one time, principles for arrangements between hospitals and physician specialists were agreed upon in joint statements between the American Hospital Association and certain medical specialty societies. The medical specialty societies have in all cases withdrawn their support for these statements so that none is currently in effect.

The American Hospital Association, therefore, wishes here to identify the issues and state its position on them, offering to hospitals practical suggestions where possible for the establishment of sound relations between hospitals and physician specialists.

1. First and foremost, the American Hospital Association has stated and continues to support the statement that it is the right and responsibility of both hospitals and physicians to develop on the basis of local conditions and needs, any terms of service which are fair to patients and which are designed to provide high quality care.

This freedom for hospitals and physicians in the interest of patients is of fundamental importance and transcends proprietary ethical concepts and disputed legal doctrines.

The American Hospital Association takes the position that good patient care is being and will continue to be provided in hospitals, both voluntary and governmental, under many forms of agreement.

2. The physician specialist is expected to exercise freely and completely his medical judgment and skill, and to strive constantly to promote an improvement of the quality of medical care.

The specialist's practice should be, from a standpoint of medical judgment, as independent as that of other staff members. Similarly, it is subject to review by the medical staff organization.

The freedom of the physician specialist to exercise his medical judgment and skill can be maintained under a variety of relationships which are agreeable to those concerned at the local level.

3. The American Hospital Association recognizes that certain diagnostic and therapeutic services are a vital part of the professional services rendered in a hospital.

A hospital must provide the attending physician what he needs for diagnosis and treatment in the care of his patient. As such, it must provide space, facilities, and trained personnel not only in operating rooms, delivery rooms, medical and surgical wards, but in laboratory, x-ray and other diagnostic areas as well.

The professional services provided in a hospital shall be determined by its governing body, medical staff and administration.

4. *Hospitals have the responsibility for charges to patients for hospital services.*

Whenever an in-hospital monopoly situation is created, someone besides the purveyor of the service must approve the charges to patients since total costs for hospital facilities and services are of concern to the governing body and the public.

Since it is the responsibility of hospitals to determine which hospital services will be provided it also becomes the responsibility of the hospital, through its governing body, to determine the charges for these hospital services.

5. The physician specialist is entitled to fair remuneration for his services considering his training and experience and the level of compensation prevailing in the locality for physicians of comparable qualifications.

The following guides for hospitals in hospital-physician relationships have been developed and have been approved by the Board of Trustees of the American Hospital Association:

1. Responsibilities of Hospital and Physician Specialist.
2. Seeking and Appointing a Physician Specialist.
3. The Hospital Approach to a Physician Specialist Arrangement.
4. Formal Agreements Between Hospitals and Physician Specialists.
5. Legal Considerations in Hospital-Physician Specialist Relationships.
6. Medical Ethics and Hospital-Physician Specialist Relationships.

6. The American Hospital Association recognizes that as diagnostic and treatment services become more complex it is necessary more and more for hospitals to consult with the medical staff on matters relating to hospital-physician specialist relationships. This is particularly true: (a) regarding the specialist's selection where professional qualifications determine the individual to be selected, (b) regarding unresloved problems arising in connection with hospital and physician specialist relationships, including financial problems, and (c) regarding charges made for services.

(Approved by Board of Trustees, November 20, 1959.)

American Medical Association

The House of Delegates of the American Medical Association at the Dallas meeting received twelve resolutions on the subject of relationships between physicians and hospitals. To resolve any doubt about its position, the House did not act upon any of the resolutions but instead reaffirmed the 1951 "Guides for Conduct of Physicians in Relationships with Institutions." It also declared that "all subsequent or inconsistent actions are considered superseded."

RELATION OF PHYSICIANS AND HOSPITALS

December, 1951

So far as it can be determined on the basis of study made by the Bureau of Legal Medicine and Legislation of the American Medical Association, as a matter of law the corporate practice of medicine is illegal in most states. In almost all instances the classic example given by the courts of the type of corporate practice of a profession that is illegal is the instance in which a corporation hires a professional man and then sells his services to the public on a fee basis for the profit of the corporation. Such exceptions as there are refer to statutory legislation in several states permitting certain modifications of this general law. It must also be remembered that fee splitting with a corporation is just as unethical as fee splitting with another physician.

In addition to being guided by the laws of the various states, physicians in their relationships with hospitals must be guided by the Principles of Medical Ethics of the American Medical Association. Those sections of the Principles which have a distinct bearing on these relationships are as follows:

Chapter I, Sec. 3.—"Groups and Clinics.—The ethical principles actuating and governing a group or clinic are exactly the same as those applicable to the individual. As a group or clinic is composed of individual physicians, each of whom, whether employer, employee or partner, is subject to the principles of ethics herein elaborated, the uniting into a business or professional organization does not relieve them either individually or as a group from the obligation they assume when entering the profession."

Chapter III. Article VI. Sec. 2.—"Conditions of Medical Practice.—A physician should not dispose of his service under conditions that make it impossible to render adequate service to his patients, except under circumstances in which the patients concerned might be deprived of immediately necessary care.

Chapter III. Article VI. Sec. 3.—"Contract practices.—Contract practice as applied to medicine means the practice of medicine under an agreement between a physician or a group of physicians, as principles or agents, and a corporation, organization, political subdivision or individual, whereby partial or full medical services are provided for a group or class of individuals on the basis of a fee schedule, or for a salary or for a fixed rate per capita.

"Contract practice per se is not unethical. Contract practice is unethical if it permits of features or conditions that are declared unethical in these Principles of Medical Ethics or if the contract or any of its provisions causes deterioration of the quality of the medical services rendered."

Chapter III. Article VI. Sec. 6.—"Purveyal of Medical Service.—A physician should not dispose of his professional attainments or services to any hospital, lay body, organization, group or individual, by whatever name called, or however organized, under terms or conditions which permit exploitation of the services of the physician for the financial profit of the agency concerned. Such a procedure is beneath the dignity of professional practice and is harmful alike to the profession of medicine and the welfare of the people."

In conclusion, the Principles of Medical Ethics states: "These principles of medical ethics have been and are set down primarily for the good of the public and should be observed in such a manner as shall merit and receive the endorsement of the community . . ."

The duties of the Judicial Council are specified in the Constitution and Bylaws and among those duties the following is prescribed:

"The Council shall have jurisdiction on all questions of medical ethics and the interpretation of the laws of the Association.

"The Council at its discretion may investigate general professional conditions and all matters pertaining to the relations of physicians to one another and to the public, and may make such recommendations to the House of Delegates or the constituent associations as it deems necessary.

"The Council shall have authority to request the President to appoint investigating juries to which it may refer complaints or evidence of unethical conduct which in its judgment are of greater than local concern. Such investigating juries, if probable cause for action be shown, shall submit formal charges to the President, who shall appoint a prosecutor to prosecute such charges against the accused before the Judicial Council in the

name and on behalf of the American Medical Association. The Council may acquit, admonish, suspend or expel the accused."

The primary obligation of both physicians and hospitals is to serve the best interest of the patients. The decision as to the ethical or unethical nature of practice must be based on the ultimate effect for good or ill on the public as a whole. All of the various questions involved in the relationship between physicians and hospitals, both legal and ethical, particularly questions dependent on local conditions, must be considered in the first instance at the local level because of the various differences which of necessity exist in the many sections of the country.

One of the factors that has aggravated physician-hospital relationship is the inclusion of medical services in the contracts of voluntary hospital service plans. The medical profession is fostering voluntary health insurance, and we believe that nothing should be done to disturb this very important and essential program. However, the American Medical Association has reaffirmed many times through its then Bureau of Medical Economics, its Judicial Council and the House of Delegates the principle that hospital service plans should exclude all medical services, and the contract provisions of such plans should be limited exclusively to hospital services. At the same time, so that there would be no misunderstanding as to which services should or should not be included, the House of Delegates has stated that ". . . if hospital service is limited to include only hospital room accommodations, such as bed, board, operating room, medicine, surgical dressings and general nursing care, the distinction between hospital service and medical service will be clear." (Proceedings of the San Francisco Session of the House of Delegates, 1938, p. 31). Past actions of the House of Delegates give every reason to reiterate that radiology, anesthesiology, pathology and physiatry constitute the practice of medicine.

In order to initiate a method for remedying this situation, it is recommended that Blue Shield and Blue Cross be requested to cooperate to the extent of writing all new contracts in such a manner that Blue Shield will cover insurable medical services and Blue Cross will cover insurable hospital services. It is hoped that the professional and hospital authorities and the voluntary prepayment plans will cooperate in furthering these recommendations.

Since the physician and hospital are interdependent, it is incumbent on both to be interested in all phases of their scientific and financial relationships. This means that the professional staff of the hospital has very definite responsibilities toward not only other members of the professional staff, whether active or courtesy, but also toward hospital management. The recommendations of the staff concerning medical matters are usually accepted by the management of the hospital through its board of managers or trustees. It must also be remembered that to be approved for residencies in specialties by the American Medical Association and the American College of Surgeons, certain requirements are mandatory to the institution, among them adequate pathologic and radiologic coverage. As a rule, the staff of a hospital elects an executive committee or works under an appointed executive committee to advise the lay officers of the institution on purely professional matters, and recommends who may or may not use the institution for professional work. Unfortunately, in many instances, the financial problems of the lay hospital management have been no affair of the staff or of its professional executive committee. This is wrong and probably the cause of most of the differences of opinion between physicians and hospital management. The financial problems of an institution in which a physician does his professional work are definitely of importance to him and to the professional staff, and the proper consideration must be given to these problems if the hospital is to work efficiently and remain the workshop of the physician, and without proper facilities the services rendered to the public are in jeopardy and these public services are the all-important function of both hospital and staff.

*Neither the hospital management nor the medical staff has the privilege or the right to make compulsory assessments of members of the medical staff for building funds or to demand an audit of staff members' personal financial records as a requisite for staff appointment.

Every professional man on the appointed staff should have a voice in the professional management of the institution. The pathologist, roentgenologist, anesthesiologist and physiatrist, as well as the other professional staff members, should have equal standing as active members of the staff with all the rights and privileges pertaining to other members of the staff of equal standing. The chiefs of these departments should be nominated and appointed in the same manner as are the chiefs of other major departments in the same hospital.

The revised Principles of Medical Ethics has been written with all of these various factors in mind and is broad enough to cover all possible ethical physician-hospital relationships. The Constitution and Bylaws of the American Medical Association distinctly covers methods of procedure for all persons who have a complaint so that they may approach the Judicial Council. The functions of that Council are specifically delineated.

"In the event of a controversy between physician and physician, or physician and hospital management, on these problems, it is recommended that, since local conditions must be taken into consideration, these problems be resolved insofar as possible at the local level.

*1958 amendment, in accordance with Resolution No. 55, House of Delegates, American Medical Association, June Session 1958.

"There can be no exploitation of the doctor or of the hospital if everyone concerned in management and on the professional staff will work together to supply the greatest possible good quality medical and hospital services to the public. In any given controversy, every effort should first be made to settle the matter at the staff-management level. In case of failure to settle the controversy at this level, assistance of the county medical society should be requested. If, then, it cannot be resolved it should be submitted to a committee of the state medical association for advice and recommendation. If problems cannot be solved at the staff-management level, through the county medical society, or through the state medical association, the Constitution and Bylaws of the American Medical Association provides that ". . . the (Judicial) Council, at its discretion, may investigate general professional conditions and all matters pertaining to the relations of physicians to one another and to the public, and may make such recommendations to the House of Delegates or the constituent associations as it deems necessary."

To implement the settlement of such controversies, it is recommended that each component medical society and each constituent state and territorial medical association appoint a Committee on Hospital and Professional Relations. This committee should be available to receive complaints from any physician, hospital, medical organization, or any other interested person or group with reference to professional or economic relations existing between doctors of medicine and hospitals. On receipt of such complaint by such a committee the matter should be investigated and acted on in such manner as will best effect adjustment of the complaint.

Another approach that should not be neglected in activating this report is that of the local and state hospital associations. Most of the states and many communities have hospital associations providing direct representation for the hospitals within their areas. It seems reasonable to assume that state medical associations and component county medical societies could well effect liaison with these organizations in the settlement of problems involving physician relationships.

In summary, the following general principles are suggested to individual physicians, county medical societies, and state medical associations as a basis for adjusting controversies, these principles, however, to be qualified to the extent required by the applicability of one or more of the factors heretofore mentioned:

1. A physician should not dispose of his professional attainments or services to any hospital, corporation or lay body by whatever name called or however organized under terms or conditions which permit the sale of the services of that physician by such agency for a fee.
2. Where a hospital is not selling the services of a physician, the financial arrangement if any between the hospital and the physician properly may be placed on any mutually satisfactory basis. This refers to the remuneration of a physician for teaching or research or charitable services or the like. Corporations or other lay bodies properly may provide such services and employ or otherwise engage doctors for those purposes.
3. The practice of anesthesiology, pathology, physical medicine and radiology are an integral part of the practice of medicine in the same category as the practice of surgery, internal medicine or any other designated field of medicine.

Minnesota State Medical Association

RESOLUTION

Whereas, a wise and foresighted legislature of the State of Minnesota has written laws in Minnesota prohibiting the practice of medicine by corporations and individuals not licensed physicians, and

Whereas, the American Medical Association has repeatedly studied the problem and has stated in 1943 that the "House of Delegates of the American Medical Association is opposed to the division of any branch of medical practice into so-called technical and profession factions," and later in 1951, that "the practice of anesthesiology, pathology, physical medicine and radiology are an integral part of the practice of medicine in the same category as the practice of surgery, internal medicine or any other designated field of medicine," and in 1955 reaffirmed its position on these matters.

Therefore Be It Resolved that the Minnesota State Medical Association first, officially recognizes the specialty of Anatomical and Clinical Pathology as the practice of medicine; second, reaffirms the philosophy that in-hospital and outpatient diagnostic laboratory services are in fact the practice of medicine and thirdly, in future contracts or actions relating to laboratory medicine actively reaffirms the belief in the legal control of all medical laboratory facilities in the State of Minnesota by licensed doctors of medicine.

Passed by: (1) Commitee on Hospital and Physician Relationships, (2) Committee on Resolutions, and (3) House of Delegates Minnesota State Medical Society, May 23, 1958.

THE SIXTIES DECADE OF DECISION

There is a revolution going on in your own backyard—a revolution that within ten years could alter your whole life, determine how you practice medicine, and dictate the way you care for your patients, reports the PR DOCTOR.

The crisis will come in the '60's, perhaps within a matter of months. The decision to be made is this: Who will take the leadership in solving medical and health problems?

This is no case of the "good guys" versus the "bad guys." It is a case of Americans looking for the best way to provide medical care for everyone. The goals on each "side" are the same, but the mechanisms for achieving them are different.

The whole revolution stems from a growing feeling that suitable medical care is not only important, it is a right to which everyone, regardless of his financial status, is entitled.

Yet people are increasingly willing to let the government assume the responsibility for health affairs. For though they bear no grudge against medical organizations, a lot of Americans feel physicians are losing this leadership by default.

In a recent survey conducted for AMA by an independent firm, the result showed that doctors, individually and collectively, are guilty of a communications failure.

The survey points up communications failures in these vital areas:

1. Failure to communicate to patients understandingly and understandably about their illnesses.
2. Failure to communicate effectively regarding fees and medical costs as they relate to other prices today.
3. Failure to communicate effectively on a personal level with patients. This leads to complaints that the doctors are cold, indifferent to people's personal problems both medical and financial; that they don't care about people's feelings, that they make people wait too long.
4. Failure to communicate the story on the long-established programs medicine has launched, that is, to train more doctors, to get these doctors into communities needing them, to police their own ranks.
5. Failure to communicate its real public interest on the case of the indigent, the aged, the economically stricken.

Part of the communications failure may be traced to doctors' commendable reticence to promote themselves and their organized projects. Many a doctor will say, "If you do a good job, people will ultimately find out about it." But "ultimately" may be too late. Politicians are wasting no time promoting unsound and undesirable schemes to "governmentalize" medicine. They know that salesmanship of a product—or a point of view—is essential today.

Today the medical profession must adapt its techniques to the times. Doctors' medical societies and allied groups must emphasize through every available means to the public that working to improve today's medical system will provide better medical care in the long run than substituting a government system.

The technique is positive action coupled with better communications.

SIX FOR THE SIXTIES MAKE SERVICE YOUR SLOGAN

1. *Service from a Personal Physician.*—Though physicians rate higher than dentists or lawyers on ethics and dedication, physicians are more often criticized in areas of personal service. Analysis of the opinion survey shows that the physician's own attitudes and motives along with the efficiency with which he runs his office are keys to service attitudes. Consequently, every physician should be aware not only of his own personal public relations, but for the public relations of the entire profession.

Needed are increased professional educational efforts on human relations techniques, ways to communicate to people more effectively, more orientation courses for new members, more refresher courses for regular members, more medical society action to establish courses in medical schools on non-scientific medical subjects.

2. *More Medical Service.*—Over one-fifth of the Americans surveyed feel there is a doctor shortage and some intimate the profession actually limits supply. About one-fourth indicate a local need for more hospital facilities. Problems appear greater in rural areas.

Needed are all-out publicity on medicine's recently stated positive policy regarding recruiting more young people into medical careers, offering medical scholarships, expanding medical schools, and ultimately training more doctors, joint efforts by medical societies and medical schools working together to tell what's being done to increase the number of medical graduates, local studies on ways to expand facilities, set up scholarships, as recommended at AMA's Dallas clinical meeting, and an awareness that the public interest is not served when medical societies and medical schools can't get along together.

3. *Better Medical Service.*—Lack of prompt service properly administered coupled with the criticism that you can't always get a doctor when you need one, are at the root of much of the criticism of the medical profession, the survey says.

Needed are more educational programs to stress the importance of securing a family doctor before emergencies arise, repeated study of grievance committees to make sure they are functioning effectively and that people know they exist, continued emphasis on office efficiency to reduce service complaints related to unnecessary waits, difficulty of access to a doctor, lack of adequate time for patients.

4. *Service at Reasonable Price.*—The weakness of medical efforts to communicate the true story on medical costs and resultant lack of understanding of financial motives leads to public feelings that doctors are excessively money-minded, charge more than expected, and do not try to keep charges as low as possible.

Needed are greater widespread educational efforts on medical care costs in relation to other costs today, promotion of medicine's traditional guarantee to provide medical care to all, regardless of ability to pay, whether these plans are formal or informal, development of relative value studies as recommended by AMA's House of Delegates among societies in this aspect of cost, continued education of individual physicians on the importance of itemizing medical bills, initiating advance fee discussions, cutting costs where possible for patients, increased emphasis on using not abusing health insurance plans and promotion of wider insurance coverage.

5. *Service Beyond the Call of Duty.*—Today doctors are less often credited than are dentists or lawyers with trying to help solve community problems. Medical societies should tackle at least one positive community service project in 1960.

6. *Service as Citizens.*—1960 is an election year. Consequently, doctors as private citizens should actively encourage people to vote, work in the political parties of their choice, and generally work for good government. It is as important for medicine to support sound legislation as it is to oppose unsound bills.

The first specific aldosterone-blocking agent...

ALDACTONE™

effectively extends the medical control of edema or ascites. It introduces a new therapeutic principle in the treatment of...

CONGESTIVE HEART FAILURE • HEPATIC CIRRHOSIS THE NEPHROTIC SYNDROME • IDIOPATHIC EDEMA

ALDACTONE introduces a new class of therapeutic agent, the aldosterone-blocking agent providing:

satisfactory relief of resistant or advanced edema even when all other agents, alone or in combination, are ineffective or are only partially effective.

A New Order of Therapeutic Activity

ALDACTONE acts by blocking the effect of aldosterone, the principal mineralocorticoid governing the reabsorption of sodium and water in the distal segment of the renal tubules.

By so doing Aldactone establishes a fundamentally new and effective approach to the control of edema or ascites, including edema resistant or unresponsive to conventional diuretic agents.

Further, because of its different site and mode of action in the renal tubules, Aldactone has a true, highly valuable synergistic activity when used with a mercurial or thiazide diuretic.

What Physicians May Expect of Aldactone

It is fully expected that Aldactone will change present medical concepts of the therapeutic limitations of managing edema. Many patients living in a greater or lesser state of edematous invalidism can now be edema-free. To others, gravely ill, Aldactone will be life-saving.

When used alone, Aldactone will produce a satisfactory diuresis in about half of those patients whose edema is resistant to conventional diuretic agents.

When Aldactone is used in a comprehensive therapeutic regimen, which includes a mercurial or a thiazide diuretic, a satisfactory diuresis and relief of edema may be expected in approximately 85 per cent of edematous patients *who would not otherwise respond.*

DOSAGE: For most adult patients the optimal dosage of Aldactone, brand of spironolactone, is 100 mg. four times daily. Aldactone should be administered for at least four or five days before appraising the initial response, since the onset of therapeutic effect is gradual when it is used alone. Aldactone manifests accelerated activity with greater response as early as the first and second days when used in combination with a mercurial or thiazide diuretic.

SUPPLIED: Aldactone is supplied as compression-coated yellow tablets of 100 mg.

BLOOD CHOLESTEROL AND FOODS

Addition of unsaturated fats and oils to the otherwise unchanged ordinary diet will not reduce blood cholesterol and prevent heart attacks and strokes, the Food and Drug Administration said today. Representations to the public that salad oils, shortenings, oleomargarine, and similar products have value for these purposes are false and misleading and will cause such products to be misbranded, FDA declared in a statement of law-enforcement policy published in today's Federal Register.

George P. Larrick, commissioner of Food and Drugs, said there is widespread interest in the possible relationship between blood cholesterol levels and heart and artery diseases. As a result, he explained, reference to the term "cholesterol" in the labeling of common foods now being offered to the public may have the effect of a claim of special value for preventing or treating these diseases.

Commissioner Larrick added: "Scientific investigations of fatty substances as a possible factor in lowering blood cholesterol and preventing heart disease should be continued, and this policy statement does not interfere in any way with legitimate research and clinical evaluation of unsaturated fats in the diet. It is our responsibility, however, to point out that the public has been misled into relying prematurely on data which are still experimental, incomplete, and contradictory, and to head off false and misleading promotions based on such data."

Cholesterol, FDA explained, is a substance that is manufactured in the body and has an important function in many of the body tissues. It is also present in animal fats and oils such as butter, lard, bacon, and meat fat. The blood level of cholesterol is controlled largely by synthesis in the body and is affected very little by the amount present in our foods.

FDA further pointed out the view of nutrition scientists that it is impracticable for a person to add enough unsaturated fats to an otherwise unchanged diet to bring about any significant change in blood cholesterol. Increased weight they add, is the only result that is likely to be achieved by increasing the intake of fats.

The FDA policy statement, based on an extensive survey of leading medical authorities, follows:

§3.41 Status of articles offered to the general public for the control or reduction of blood cholesterol levels and for the prevention and treatment of heart and artery disease under the Federal Food, Drug, and Cosmetic Act.

(a) There is much public interest and speculation about the effect of various fatty foods on blood cholesterol and the relationship between blood cholesterol levels and diseases of the heart and arteries. The general public has come to associate the term "cholesterol" with these diseases. A number of common food fats and oils and some other forms of fatty substances are being offered to the general public as being of value in the control or reduction of blood cholesterol levels and for the prevention or treatment of diseases of the heart or arteries.

(a) The role of cholesterol in heart and artery diseases has not been established. A causal relationship between blood cholesterol levels and these diseases has not been proved. The advisability of making extensive changes in the nature of the dietary fat intake of the people of this country has not been demonstrated.

(c) It is therefore the opinion of the Food and Drug Administration that any claim, direct or implied, in the labeling of fats and oils or other fatty substances offered to the general public that they will prevent, mitigate, or cure diseases of the heart or arteries is false or misleading, and constitutes misbranding within the meaning of the Federal Food, Drug, and Cosmetic Act.

This Section is for you to voice your convictions, comments, and queries on all subjects political, economic, historic, humorous, scientific or otherwise, to many physicians. Writings not sufficiently formal and too brief for an editorial or a scientific manuscript are requested. Clinical and research observations, no matter how brief, similar to those in *The Lancet* (London), are particularly encouraged.

REPLY TO FOOD AND DRUG ADMINISTRATION STATEMENT

The Food and Drug Administration has stated that some recent advertising for unsaturated fats, including vegetable oils, was "false and misleading."

Our position has been that research results are definitely in favor of the beneficial effects of unsaturated fats in the diet and that the public should be made aware of this evidence.

The research findings of many leading medical and nutritional authorities are on public record emphasizing the importance of vegetable oils not as "additions" but as replacements for other fats in the diet. Our own evaluations and our sponsorship of resarch in this field began more than a decade ago, but we refrained from public statements until we believed the results were well substantiated.

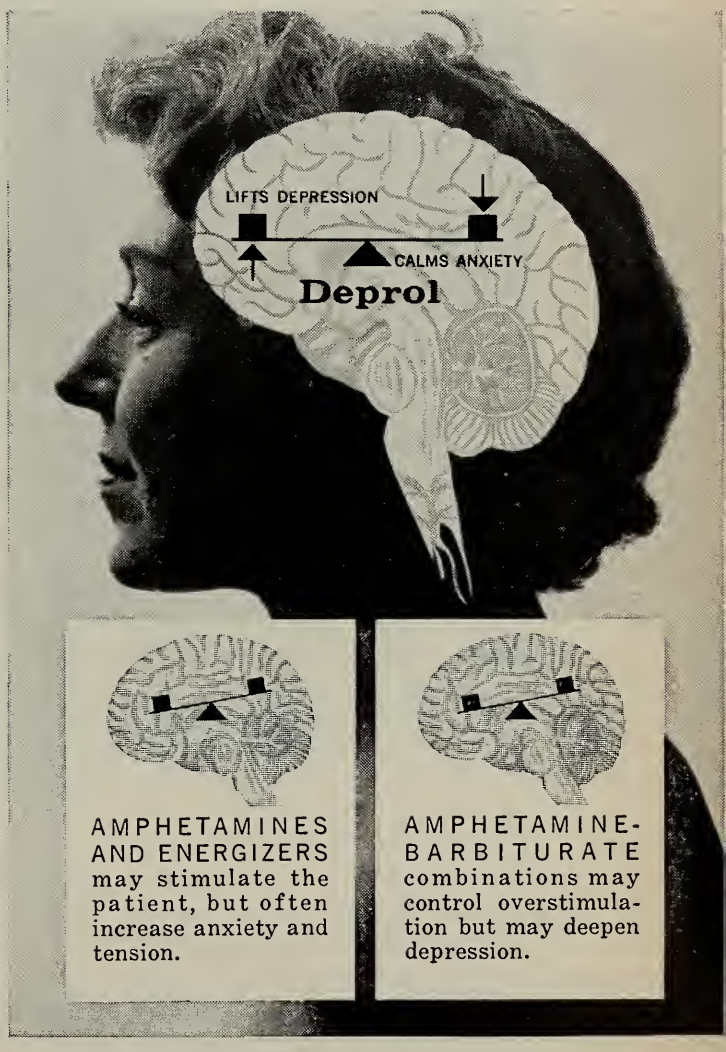
as it calms anxiety!



Smooth, balanced action lifts depression as it calms anxiety... swiftly and safely

Balances the mood — no "seesaw" effect of amphetamine-barbiturates and energizers. While amphetamines and energizers may stimulate the patient — *they often aggravate anxiety and tension.* And although amphetamine-barbiturate combinations may counteract excessive stimulation — *they often deepen depression.*

In contrast to such "seesaw" effects, Deprol lifts depression as it calms anxiety — both at the same time.

Acts swiftly — the patient often feels better within a few days. Unlike the delayed action of other drugs which may take two to six weeks to bring results, Deprol's smooth, immediate action relieves the patient quickly — often within a few days.

Acts safely — no danger of liver damage. Deprol does not produce liver damage, hypotension, psychotic reactions or changes in sexual function — frequently reported with other drugs.

REPLY TO FOOD AND DRUG ADMINISTRATION STATEMENT

(Continued from Page A-62)

The Department of Health, Education and Welfare, through the Public Health Service, in 1957 began public distribution of a bulletin, currently in circulation, titled "The Food You Eat and Heart Disease."* Among the quotations from this pamphlet are some very positive statements relating to cholesterol levels, and unsaturated fats. . . .

"Most medical scientists now agree that there is a relation between the amount of cholesterol in the blood and the depositing of fat in the blood vessels. . . ."

"Some fats in the diet actually lower blood cholesterol, while other fats raise the level in the blood. It is not yet entirely clear why this is so. Current experiments indicate that the degree of 'saturation' of the fats may be a factor. . . ."

At about the same time this pamphlet was issued, on the basis of the evidence, we first introduced the subject in our advertising.

With the increasing evidence of the beneficial role of unsaturated fats in the diet, there is strong public demand for other products which will reduce blood cholesterol. The National Research Council has called for such developments, saying that "shortening and margarine producers should re-evaluate the merits of blended fats and anticipate the problems that will be raised by increased demand for such fats." Accordingly, we have created a new and superior margarine, high in polyunsaturates, containing pure liquid corn oil. This product, Cornette margarine, is now in major test markets and we plan to make it widely available in the near future.

Certainly, nothing the FDA has said detracts from the wholesome, nutritious, and flavorful qualities of either Mazola corn oil or Cornette margarine. We are, of course, co-operating with the Food and Drug Administration. But because of tremendous public interest in the ultimate truth, Corn Products Company will continue to sponsor research in the field of nutrition. We will use every opportunity to bring the results to the attention of the government, medical authorities, and the general public.

This flaky pie crust, *crisp cookies, Chiffon cakes, biscuits can all be made easily with Wesson. Decrease the calories of pie by preparing with single crust and a fresh fruit or gelatin filling. It is delicious.*

FREE *Wesson recipes are available in quantity for your patients, showing them how to prepare these treats as well as main dishes, vegetables and salads with poly-unsaturated vegetable oil. Request quantity needed from The Wesson People, Dept. N., 210 Baronne St., New Orleans 12, La.*

Wesson satisfies the most exacting appetites. To be effective, a diet must be *eaten* by the patient. The majority of housewives prefer Wesson particularly by the criteria of odor, flavor (blandness) and lightness .of color. (Substantiated by sales leadership for 59 years and reconfirmed by recent tests against the next leading brand with brand identification removed, among a national probability sample.)

Wesson's Important Constituents

Wesson is 100% cottonseed oil . . . winterized and of selected quality

Linoleic acid glycerides (poly-unsaturated)	50-55%
Oleic acid glycerides (mono-unsaturated)	19-28%
Total unsaturated	75-80%
Palmitic and stearic glycerides (saturated)	20-25%
Phytosterol (predominantly beta sitosterol)	0.4-0.7%
Total tocopherols	0.09-0.12%

Never hydrogenated—completely salt free

Each pint of Wesson contains 437-524 Int. Units of Vitamin E.

Woman's Auxiliary

BLUE EARTH VALLEY MEDICAL AUXILIARY OFFERS NURSING SCHOLARSHIP

Again this year, the Woman's Auxiliary to the Blue Earth Valley Medical Society is offering a nursing scholarship. To the senior high school girl from Faribault county $100 will be given on the day she receives her cap from an accredited Minnesota hospital or school of nursing. The only reservations are that the girl must have spent the senior year in the high school from which she is graduating, and if she has already won a local nursing scholarship, such as those offered by local hospital auxiliaries, she may not qualify.

The scholarship award is the project of a comparatively small group of women, the wives of medical doctors in Faribault, Martin and Watonwan counties. At present, the auxiliary has twenty-seven members.

The $100 gift will be offered to applicants from Faribault county.

Application forms went to the school principals in every high school in Faribault county. Application may be secured by writing to the Scholarship Committee, Mrs. Mark Virnig, Wells, Minnesota.

Completed applications had to be sent in by March 15.

RAMSEY COUNTY AUXILIARY NEWS

The February Board Meeting was called to order by Mrs. William Menold, vice president. Mrs. Coleman Connolly informed the members that the dinner-dance given by the Auxiliary at the Town and Country Club was a financial success and Mrs. Rodney F. Sturley thanked the members of her committee for their help. The party was a very pleasant, informal one, and one that we hope will be a yearly event.

Mrs. Davitt Felder explained the importance of the Smathers-Keogh-Simpson Bill. During the meeting members wrote letters in favor of the Bill to Senator Eugene J. McCarthy. Mrs. Felder also asked members to acquaint themselves with the Forand Bill so that when the time comes they will be familiar with it and will be able to write to their congressman.

Dr. Brian J. McGroarty will give a talk on Blue Shield at the March meeting which will be held in the Minnesota Club.

State president-elect, Betty Gardner, will take a leave of absence from her Auxiliary duties, to attend the National Curling meet in Chicago. Betty is a member of the Bonnie Spielers team which will take part in the competition.

ZUMBRO VALLEY MEDICAL AUXILIARY HEARS TWO TALKS ON ISRAEL, HOLLAND

The Zumbro Valley Medical Auxiliary held its quarterly meeting recently at the Mayo Foundation House.

Guest speakers on the program entitled "Know My Country," were Dr. Henry Neufeld and Dr. C. A. Wagenvoort. Both are on special appointments in the Mayo Foundation.

Dr. Neufeld, a senior cardiologist from Tel-Hashomer Government Hospital in Israel, talked on "Inside Israel." He traced the historical development of Israel, told of its growth during the past ten years and showed slides of Tel-Aviv, Haifa and Jerusalem.

Dr. Wagenvoort, chief pathologist at the State University in Leyden, Holland, talked on "Inside Holland." He said Holland is a sea-faring nation and has at Rotterdam the greatest harbor in the world with the exception of New York City. His listeners were surprised when he said Holland is the most densely populated country in the world. He said its people have made the best use of their land for agriculture and a few years ago started the Delta Plan to safeguard the coast line.

Preceding the program, coffee was served to the fifty members and guests present.

SCOTT-CARVER MEDICAL AUXILIARY NEWS

The Scott-Carver Medical Auxiliary is happy to announce that it now has 100 per cent membership. The Scott-Carver Auxiliary President is Mrs. E. M. Doherty, New Prague, Minnesota.

HENNEPIN COUNTY "CAROUSEL" SET

The annual "Carousel" style show and brunch sponsored by the Woman's Auxiliary to the Hennepin County Medical Society and produced by the Dayton Oval Room, will be held April 27 and 28 at 9:30 a.m. in the Dayton Sky Room.

This is the only fund-raising project undertaken by the Hennepin County Auxiliary and by this its many philanthropies are supported.

Tickets are $3.25 each and may be secured by writing to Mrs. Henry Quist, Jr., 4116 Glencrest Road, Minneapolis 16, Minnesota. There will be favors for all, some very special door prizes and, of course, up-to-the-minute styles to be enjoyed. Members are urged to make reservations now.

AUXILIARY WILL DISTRIBUTE HEALTH CAREERS PACKETS

Health Career Packets, prepared by the Minnesota State Medical Association, allied career groups, and the Minnesota State Department of Health, will be distributed by members of the Woman's Auxiliary to all state private and public high schools, according to announcement by Mrs. Roy C. Pedersen, State Paramedical Careers Chairman.

The packets are attractive folders which contain recruiting material for all the allied medical careers including medicine. Private groups were solicited to pay for the cost of the packets.

All Auxiliary presidents and paramedical chairmen have been asked by Mrs. Pedersen to co-operate in the project. They will distribute one packet to the high school principal or guidance counselor and another one to the school library. The library copy will be used exclusively by the students. About 1,000 packets should be distributed throughout the state by Auxiliary members.

In Memoriam

WINCHELL McK. CRAIG

Dr. Winchell McK. Craig, neurologic surgeon, former head of the Section of Neurologic Surgery at the Mayo Clinic and professor of neurologic surgery in the Mayo Foundation, Graduate School, University of Minnesota, died February 12, 1960. He was sixty-seven years old.

Doctor Craig born in Washington Court House, Ohio, was a student at the Culver Military Academy. In 1915, he received the degree of Bachelor of Arts from the Ohio Wesleyan University. In 1919, he was awarded the degree of Doctor of Medicine by the Johns Hopkins University.

Doctor Craig came to Rochester on July 1, 1921, as a fellow in surgery of the Mayo Foundation.

He was appointed a first assistant in neurology in 1924, and on April 1, 1926, he became a member of the staff as a neurologic surgeon. He was head of the Section of Neurologic Surgery in the Mayo Clinic from 1946 to April 1, 1955, when he became a senior consultant, and he retired from active practice on July 1, 1957, after thirty-one years as a member of the staff. In the same year, Doctor Craig was named director of civil defense of the city of Rochester. In June, 1959, Dr. Craig was appointed a field representative of the Council on Medical Education and Hospitals of the American Medical Association. He resigned this post in November of the same year to accept the appointment of special assistant for health and medical affairs to the Secretary of Health, Education and Welfare, U. S. Government.

Doctor Craig was appointed an instructor in neurologic surgery in the Mayo Foundation, Graduate School, University of Minnesota, in 1927, and was advanced to the grades of assistant professor in 1929, associate professor in 1932 and professor in 1937.

In 1945, Doctor Craig became the first physician from civilian life in the history of the U. S. Navy to reach the grade of rear admiral.

An Associate member of the Minnesota State Medical Association and the Zumbro Valley Medical Society, Doctor Craig was a fellow in the American Medical Association and the American College of Surgeons, and a member of the American Surgical Association, the American Neurological Association, the Western Surgical Association, the Southern Surgical Association, the Minnesota Society of Neurology and Psychiatry, the International Surgical Society, the Central Neuropsychiatric Association, the Central Society for Clinical Research, the Johns Hopkins Alumni Association, the Alumni Association of the Mayo Foundation, the Minnesota Surgical Society, the International Neurological Association, the American Legion, the Reserve Officers' Association of the United States, the Ohio Society of New York, the Beta Theta Phi academic fraternity and the Phi Beta Pi professional medical fraternity. He was an honorary member of the American Academy of Neurological Surgery. He was a member of the editorial staff of *The Journal of Neurosurgery* and the special advisory board to *Postgraduate Medicine*. In 1956, he was elected president of the Mayo Foundation chapter of the Society of the Sigma Xi. He served as chairman of the American Board of Neurological Surgery, Inc., and as a member of the Board of Trustees of the Ohio Wesleyan University.

Survivors include his wife, Jean Katherine, four children, Lieutenant Winchell McKendree Craig, of the U. S. Marine Corps, San Diego, California, James Stewart Craig, a student at the University of Minnesota, Jeanne Mary Patricia Craig, a student nurse completing her work at the University of Oregon, and Graham Fitzgerald Craig, also a student at the University of Minnesota; and two brothers, Thomas H. and Robert A., who reside in Washington Court House, Ohio.

ESKIL ERICKSON

Dr. Eskil Erickson, Halstad physician and surgeon, died February 19, 1960, at the age of fifty-nine years.

He was born in Wheaton and was a graduate of the University of Minnesota Medical School, serving his internship at Ancker Hospital in St. Paul. He had practiced in Halstad since 1931.

The deceased was a member of the Red River Valley Medical Society, the Minnesota State Medical Association and the American Medical Association.

Doctor Erickson is survived by his wife, Frances; a daughter, Karen Marie, a student at North Dakota University; two sisters, Elva and Thelma Erickson, both of St. Paul; and two brothers, Lennart, Litchfield and Holding, Wheaton.

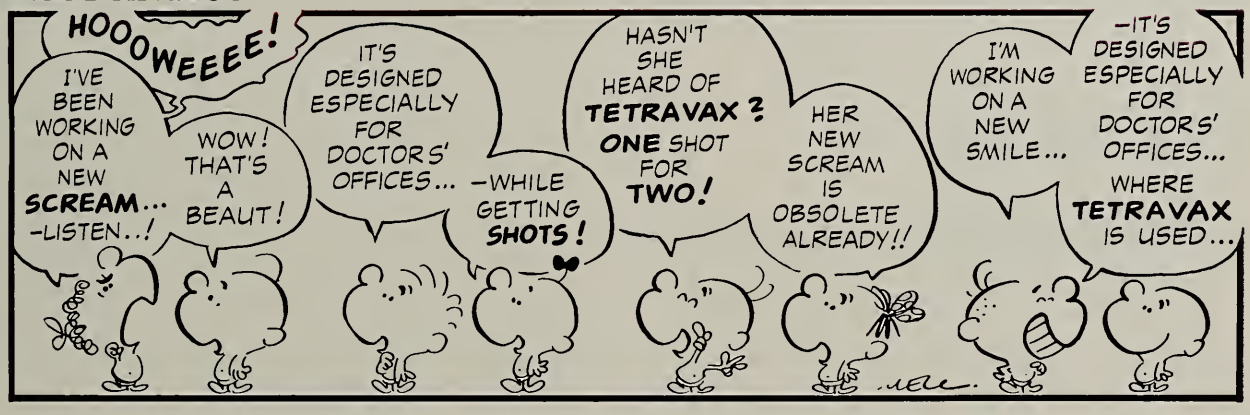
FRANK GARRETT FOLKEN

Dr. Frank Garrett Folken, Albert Lea, Eye, Ear, Nose and Throat specialist, died January 31, 1960. He was sixty-seven years old at the time of his death.

Born in Schuyler, Nebraska, Doctor Folken was a graduate of the University of Nebraska Medical School. He served as a Lieutenant in the Navy at Great Lakes during World War I.

He came to Albert Lea in 1919. Doctor Folken was in general practice there for five years and then took specialized study at the University of Vienna in Eye, Ear, Nose and Throat, and upon his return to Albert Lea specialized in Eye, Ear, Nose and Throat until he retired in 1959.

He was a member of Christ Episcopal Church and had served as a vestryman and senior warden of the church.



He was a member of the American College of Surgeons, the American Medical Association, the Minnesota State Medical Association, the Freeborn County

Iron

In a semi-fluid state—it's quickly absorbed and well tolerated

Hematovals therapy for refractory hypochromic anemia provides semi-fluid iron in a soft, elastic capsule for rapid absorption without gastric irritation.

Each capsule supplies 58 mg. of ferrous ionic iron. Normal blood levels are quickly restored. Achlorhydria does not complicate Hematovals therapy because the iron remains in the ferrous state during conversion.

The cobalt factor induces better hemoglobin synthesis and quicker response. Hematovals also contain vitamin B_{12}, folic acid, liver and B-complex factors to help overcome anorexia. Assimilation is assisted by the ascorbic acid present in each Hematoval.

EACH CAPSULE CONTAINS:

Ferrous Sulfate, 4.5 gr.
Iron.....58 mg.
Cobalt Sulfate 2.0 mg.
Cobalt.....0.4 mg.
Liver, Desiccated, N.F.....110 mg.
Vitamin B_{12}.....1 mcg.
Folic Acid.....0.25 mg.
Thiamine Mononitrate.....1 mg.
Riboflavin.....1 mg.
Pyridoxine Hydrochloride.0.25 mg.
Calcium Pantothenate....0.25 mg.
Nicotinamide.....3.3 mg.
Ascorbic Acid.....16.66 mg.

FRANK GARRETT FOLKEN

(Continued from Page A-82)

Medical Society and was a Diplomat of the American Academy of Ophthalmology and Otorhinolaryngology.

He was a member of the Kiwanis Club, the Elks Lodge, the Masonic orders, the 40 and 8 and the American Legion. He was a past commander of the Legion. Immediate survivors are his wife, Rita; one daughter, Mrs. T. M. (Sue) Gill, and three grandchildren, John, Ann and Peter Gill; one brother, Heio Folken, Hastings, Nebraska and two sisters, Mrs. Hugo Alphers, Long Beach, California, and Mrs. Henry Henrichs, Allison, Iowa.

ARVID CLAUS LINDBERG

Dr. Arvid Claus Lindberg, a practicing Minneapolis physician for nearly forty years, died January 20, 1960, at the age of eighty-one years.

A native of Harris, Minnesota, Doctor Lindberg was graduated from the University of Minnesota Medical School in 1908. He was elected to honorary membership in Sigma Xi scientific fraternity.

He practiced general medicine in North Branch, Minnesota, until 1919. He then took postgraduate training in eye, ear, nose and throat diseases in New York and Washington. He opened his Minneapolis practice in 1921 and retired in his eightieth year.

Doctor Lindberg was a Life Member of the Minnesota State Medical Association. He was also a member of the Hennepin County Medical Society and the American Medical Association.

Survivors include a son, Dr. Winston, Minneapolis, and a brother, F. A. Lindberg, Harris.

ALBERT M. SNELL

Dr. Albert M. Snell, specialist in internal medicine, died in Palo Alto, California, on February 6, 1960, at the age of sixty-three years. Doctor Snell was born at Lake Park, Minnesota, and received the degree of Bachelor of Science in 1916 and that of Doctor of Medicine in 1918, from the University of Minnesota. He then served at the United States Naval Hospital at Great Lakes, Illinois, and was later medical officer of the U.S.S. *K. I. Luckenbach,* with the grade of lieutenant, junior grade.

Doctor Snell came to Rochester, Minnesota, on February 1, 1924, as a first assistant in medicine in the Mayo Clinic. He became a member of the staff of the Mayo Clinic on July 1, 1925, as a consultant in medicine, and in 1929, became head of a section of medicine in the Mayo Clinic and instructor in medicine in the Mayo Foundation, Graduate School, University of Minnesota. He was advanced to assistant professor in 1932, to associate professor in 1935 and to professor in 1939.

Doctor Snell entered into active service in the Medical Corps of the United States Naval Reserve on December 29, 1941, with the grade of commander. He was commended for meritorious service by the Secretary

of the Navy in 1946, and released from active duty on February 16, 1946, with the rank of captain. From 1946 to 1956, he was a member of the Professional Services Division and chief of a section in the Veterans Administration. He was vice chairman of the Professional Services Division in 1948 and chairman in 1953.

Doctor Snell left the Mayo Clinic in 1950 to go to the Palo Alto Clinic in Palo Alto, California. He became clinical professor of medicine in the University of California. He was a member of the Zumbro Valley Medical Society, the Minnesota State Medical Association, the American Medical Association, the American Gastroenterological Association, American Society for Clinical Investigation, the Association of American Physicians, the American Association for Experimental Pathology, the Central Interurban Clinical Club, Minnesota Society of Internal Medicine, Minnesota Academy of Medicine, Society of Sigma Xi, Alpha Omega Alpha medical honor society, Alpha Kappa Kappa professional medical fraternity and the Alumni Association of the Mayo Foundation.

Doctor Snell was married to Miss Eleanor Shea on January 4, 1921; two sons and two daughters were born to them. They are: Major Willard Snell, U. S. Marine Corps, Camp Pendleton, California; Barbara (Mrs. Malcolm McCarthy), of Hillsborough, California; Thomas Snell, of Madrid, Spain; and Miss Susan Snell.

Doctor Snell was married to Miss Alice I. Morrow on November 11, 1944. Mrs. Snell and a son, David, of Palo Alto, survive.

®FILMTAB—FILM-SEALED TABLETS, ABBOTT.

The impression that TAO is an unusually active antibiotic has steadily gained recognition by impressive clinical performance. Now come reports of **in vivo** and **in vitro** biological and biochemical evaluations that show TAO to be indeed unique.[1,2]

TAO differs from other antibiotics in that it is metabolized to multiple active compounds which remain active throughout their presence in the body. These 7 derivatives (in addition to TAO) show activity against common Gram-positive pathogens, including resistant strains of **Staph. aureus.**

In light of these findings, take another look at TAO performance: • 92% success in published cases of Gram-positive respiratory, skin, soft tissue and genitourinary infection • Effective against 78% of 64 "antibiotic-resistant" epidemic staphylococci. (In the same study, chloramphenicol was active against 52%; erythromycin against only 25%)[3] • No side effects in 94%; infrequent reactions mild and easily reversed • Quickly absorbed • Highly palatable.

Sound reasons to: Start with TAO to end 9 out of 10 common Gram-positive infections.

Supplied: TAO Capsules—250 mg., and 125 mg., bottles of 60. **TAO for Oral Suspension**—125 mg. per tsp. (5 cc.) when reconstituted; unusually palatable cherry flavor; 60 cc. bottle. Prescription only.

Other TAO forms available: TAO Pediatric Drops: flavorful, easy to administer. **TAO®-AC:** TAO analgesic, antihistaminic compound. **TAOMID®:** TAO with triple sulfas. **Intramuscular or Intravenous:** in clinical emergencies. Prescription only.

The Physician's Diary

The Moose Lake Village Council met recently at the first meeting of the new year. At the meeting the Council named **Dr. Thomas Moe, Dr. A. Sach-Rowitz, Dr. R. F. Kolosky, Dr. L. J. Stella,** and **Dr. M. S. Munson** to the Board of Health. Doctor Moe was also appointed Chairman of the Board.

* * *

The newly formed District I Hospital of Faribault recently elected **Dr. Donald J. Studer** of Faribault as Chief of Staff. Doctor Ttuder was elected, upon recommendation of the nominating committee of the Staff, by physicians who have made application and received appointment to the Staff from the Board of Trustees.

* * *

The Loretto and Union Hospital staffs of New Ulm recently elected **Dr. William J. Muesing,** as President of both staffs. Also receiving posts at the two hospitals was **Dr. Joseph W. Burnett,** New Ulm. Doctor Burnett was elected Vice President of the Union Staff and Secretary of Loretto. **Dr. Frank J. Carthey** was elected Vice President at Loretto and **Dr. C. A. Saffert,** Secretary at Union.

* * *

Dr. John S. Pearson, Mayo Clinic, has been appointed by the State Board of Health to an Advisory Committee on Human Genetics. Other members are **Dr. Sheldon C. Reed,** Dight Institute; **Dr. John A. Anderson, Dr. John E. Anderson, Dr. Ray Anderson, Dr. Robert Gorlin,** and **Dr. E. Adamson Hoebel,** University of Minnesota, and **Dr. Tague Chisholm,** Minneapolis.

* * *

Members of the Board of Health of New Ulm were recently appointed. They include **Dr. C. A. Saffert,** Health Officer; **Dr. H. A. Vogel** and **Dr. William A. Black,** members, one year term.

* * *

Dr. Malcolm A. McCannel, Minneapolis, recently announced the association of **Dr. Charles E. Tesar** and **Dr. Russell A. Thompson** in the practice of Ophthalmology and Ophthalmic Surgery.

* * *

Rochester physician, **Dr. Charles Mayo,** recently addressed a group of 800 persons. They were attending the 75th Annual Meeting of the Aberdeen, South Dakota, Chamber of Commerce. Doctor Mayo spoke on the two sides of alleged high medical costs.

* * *

The new president of the Southwest Medical Society is **Dr. Hugh D. Patterson** of Slayton. Other officers recently installed include **Dr. O. M. Heiberg,** Worthington, secretary; **Dr. B. N. Karleen,** Jackson, president-elect; and **Dr. R. K. Minge,** Worthington, vice president.

* * *

The Minnesota Association for Retarded Children honored **Dr. Dale C. Cameron** at a noon luncheon recently. **Dr. Donald Berglund,** Northfield, presented Dr. Cameron with a certificate of appreciation for his work with retarded children.

Dr. Nelson Bradley, retiring superintendent of the Willmar State Hospital, was recently honored by employes of that Hospital at a farewell party. Dr. Bradley received a plaque commending him on his work in Minnesota and it expressed regret at his leaving. It was signed by Orville Freeman, Governor of Minnesota.

* * *

The Olmsted Medical Group recently held its annual partnership meeting. At the meeting, **Dr. Harold A. Wente** was chosen to succeed **Dr. J. E. Verby** as president of the Group. Other officers are **Dr. W. R. Weyhrauch,** vice president; **Dr. J. C. Brodhun,** secretary-treasurer; and Dr. Verby, trustee.

* * *

The position as Superintendent of Willmar State Hospital left vacant by **Dr. Nelson J. Bradley** was filled recently. **Dr. Vera Mather Behrendt** of Rhode Island accepted that position and began duties on February 3.

* * *

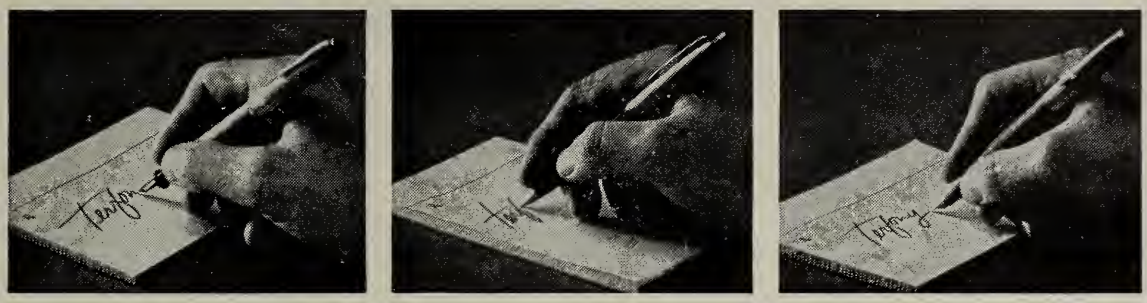
The Miller Memorial Hospital of Duluth at its recent annual medical staff meeting, installed the new chief of staff. He is **Dr. H. J. Walder,** Duluth. Dr. Walder succeeds **Dr. K. A. Storsteen** who becomes a member of the executive committee. Other new officers are **Dr. H. E. Bakkila,** vice chief of staff; **Dr. J. J. Halbert,** staff secretary; and **Dr. Dwight Hoeg,** a member of the executive committee. **Dr. Mario Fischer,** Duluth, was named ex-officio member of the executive committee.

* * *

Dr. John C. Brodhun, Olmsted Medical group member, recently attended an officers conference for component chapters of the Southern Minnesota Chapter of the Minnesota Academy of General Practice. Doctor Brodhun is vice president of the Southern Minnesota Chapter. Other officers of the Chapter are **Dr. Dale J. Hawk,** St. Charles, president; **Dr. D. W. Sontag,** Lake City, secretary-treasurer; **Dr. John O. Fluegel,** Rochester, program chairman; and **Dr. Sam McHutchison,** St. Charles, delegate.

* * *

The new Chief of Staff of the Owatonna City Hospital is **Dr. Theodore J. Stransky** of Owatonna. He succeeds **Dr. John A. McIntyre.** Other officers elected were **Dr. Donald H. Dewey,** vice president of the staff; and **Dr. James McEnaney,** secretary. Outgoing officers include **Dr. D. H. Honath,** vice president; and **Dr. D. K. Halvorsen,** secretary.



* * *

University of Minnesota heart surgeon, **Dr. C. Walton Lillehei,** left for Europe recently to give a series of lectures on open heart surgery at medical centers in England and Germany.

* * *

The medical staff of St. Joseph's Hospital, Mankato, recently elected **Dr. R. A. Sanford** president of the staff. Doctor Sanford will serve through 1960. Elected vice

The Biwabik Order of Oddfellows has offered their building to secure an independent resident physician for the town of Biwabik. The Chamber of Commerce has been interviewing physicians for that position since **Dr. S. C. Blackmore** announced the closing of his office.

* * *

Dr. Edward A. Boyden, emeritus professor of anatomy at the University of Minnesota, was among ten American medical doctors given distinguished achievement awards recently for exceptional contributions to world medical progress. Doctor Boyden is currently resident professor of anatomy at the University of Washington.

* * *

The U. S. Public Health Service has appointed **Dr. Howard P. Rome,** professor of psychiatry at the University of Minnesota's Graduate School of Medicine, Rochester, to serve a three-year term on the Selection Committee for the Senior Research Fellowship program of the National Institute of Health. Doctor Rome will advise and make recommendations to the surgeon general on the selection of qualified persons for the five-year fellowships.

* * *

Dr. C. F. Wohlrabe has been appointed health officer of North Mankato, it was announced recently. The appointment took place at the Organizational Meeting of the City Council of North Mankato.

A former member of the Mayo Clinic staff, **Dr. C. R. Holland** has opened private offices as a physician and surgeon at 512 2nd Avenue S.W., in Rochester. Doctor Holland was a consulting physician in the emergency and admitting rooms at St. Mary's Hospital until July, 1959.

* * *

The Winona County Medical Society re-elected **Dr. L. J. Wilson** as its president recently. The election took place at a business meeting conducted in conjunction with a joint session with the society's auxiliary. **Dr. L. F. Johnston** was elected secretary-treasurer to succeed **Dr. C. W. Rogers. Dr. Warren W. Haesly** was re-named vice president and **Dr. L. I. Younger** was renamed delegate to the state assembly, with **Dr. F. J. Vollmer** as alternate. New director for two years is **Dr. Sam K. McHutchison** of St. Charles. **Dr. James V. Testor** of Winona General Hospital spoke on hazards of radiation.

* * *

Appointments announced at the meeting of the Mora Village Council included **Dr. A. C. Peterson** as Health Officer, **Dr. H. L. Berge** to the Utilities Committee, and **Dr. W. Nordman** to the Airport Commission.

* * *

Dr. L. R. Parson of Elbow Lake has announced his retirement. Doctor Parson is retiring after nearly forty years of active practice as a general practitioner.

* * *

Among speakers at the recent Winter Seminar of the Minnesota Academy of General Practice at St. John's University at Collegeville were **Dr. B. Marden Black,**

professor of surgery at the Mayo Foundation; **Dr. Lyle J. Hay** and **Dr. Robert L. Vernier** of the University of Minnesota.

* * *

Dr. H. M. St. Cyr has been elected chief of staff at North Memorial Hospital in Robbinsdale. Other officers include **Dr. D. B. Simonson,** chief of staff elect and **Dr. R. J. Rotenberg,** secretary-treasurer.

* * *

Mount Sinai Hospital of Minneapolis has announced the election of **Dr. David Gaviser** as president of the medical staff for 1960. Other officers are **Dr. Earl Hill,** vice president and **Dr. Norman Bloom,** secretary-treasurer. **Dr. Isadore Fisher** and **Dr. Samuel Feinberg** were elected to the executive committee.

* * *

Dr. Philip H. Soucheray, St. Paul, announced the association of **Dr. Everett H. Karon** in the practice of internal medicine. Doctor Karon recently completed his Fellowship in internal medicine at the Mayo Clinic and is interested in diseases of the chest and allergy.

* * *

Head of the Section of Pediatrics of the Mayo Clinic, **Dr. James W. DuShane,** has been appointed to the Executive Committee of the American Heart Association. Doctor DuShane is also Chairman of the Council on Rheumatic Fever and Congenital Heart Disease of the American Heart Association.

The St. Paul Surgical Society recently celebrated its 25th Anniversary at a banquet held at the Minnesota Club in St. Paul. **Dr. Justus Ohage** presented a gavel that had been constructed from oak paneling found during reconstruction of St. Joseph's Hospital in St. Paul, the paneling being in the operating room in which the first successful Cholecystectomy in North America was performed by Dr. Justus Ohage, Sr., on September 24, 1886. Guest speaker of the evening was **Dr. Steven Economou,** associate professor of surgery at the University of Illinois. His subject was "Chemotherapy and Prevention of Cancer."

* * *

"Misleading Calcific Shadows in the Abdomen," a scientific exhibit by **Dr. Lloyd G. Bartholomew, Dr. James C. Cain, Dr. George D. Davis** and **Dr. Arthur H. Bulbulian,** all of the Mayo Clinic, was given first award at the recent annual meeting of the Interstate Postgraduate Medical Association in Chicago. Drs. Cain and Bartholomew are consultants in medicine; Dr. Davis is a consultant in diagnostic roentgenology, and Dr. Bulbulian is director of the Mayo Foundation Museum of Hygiene and Medicine.

* * *

The medical staff of Olmsted Community Hospital recently elected officers. Named president of the group was **Dr. John C. Brodhun. Dr. Theodore Wellner** is vice president and **Dr. John O. Fluegel** was elected secretary-treasurer.

Dr. Robert P. Koenig has announced the opening of an office at 410 Granite Exchange Building in St. Cloud. Doctor Koenig will limit his practice entirely to general ophthalmology and surgery of the eyes.

* * *

The Naeve Hospital of Albert Lea has announced the election of **Dr. T. M. Gill** as chief of the medical staff. Doctor Gill began his duties at the beginning of the year.

* * *

A Minneapolis physician, **Dr. David C. Halvorson,** has announced that he is now associated with **Dr. Warren E. Wilson and Dr. Bernard Street** of Northfield in the practice of medicine and surgery.

* * *

Dr. Cyrus Owen Hansen, Minneapolis, has been elected a fellow of the American College of Radiology for outstanding contributions and service to radiology. He received the fellowship degree at a convocation recently in New Orleans, Louisiana.

* * *

Elbow Lake, Minnesota, has a new physician. He is **Dr. Dale C. Lindquist.** Doctor Lindquist will enter a partnership with **Dr. V. A. Doms** and **Dr. C. F. Peikert,** at the Elbow Lake Clinic.

* * *

Dr. John Hetzler will begin practice in Pine Island, Minnesota, on or about July 1, 1960. The community of Pine Island is building a new doctor's office for thei new physician. The building is expected to be ready fo occupancy when the physician arrives.

* * *

A former associate of **Dr. Paul A. Swedenburg** at th Swedenburg Clinic at Glenwood, **Dr. B. A. Kolp,** recently announced that he has opened his own office for th practice of medicine. Doctor Kolp will also practice i Glenwood.

* * *

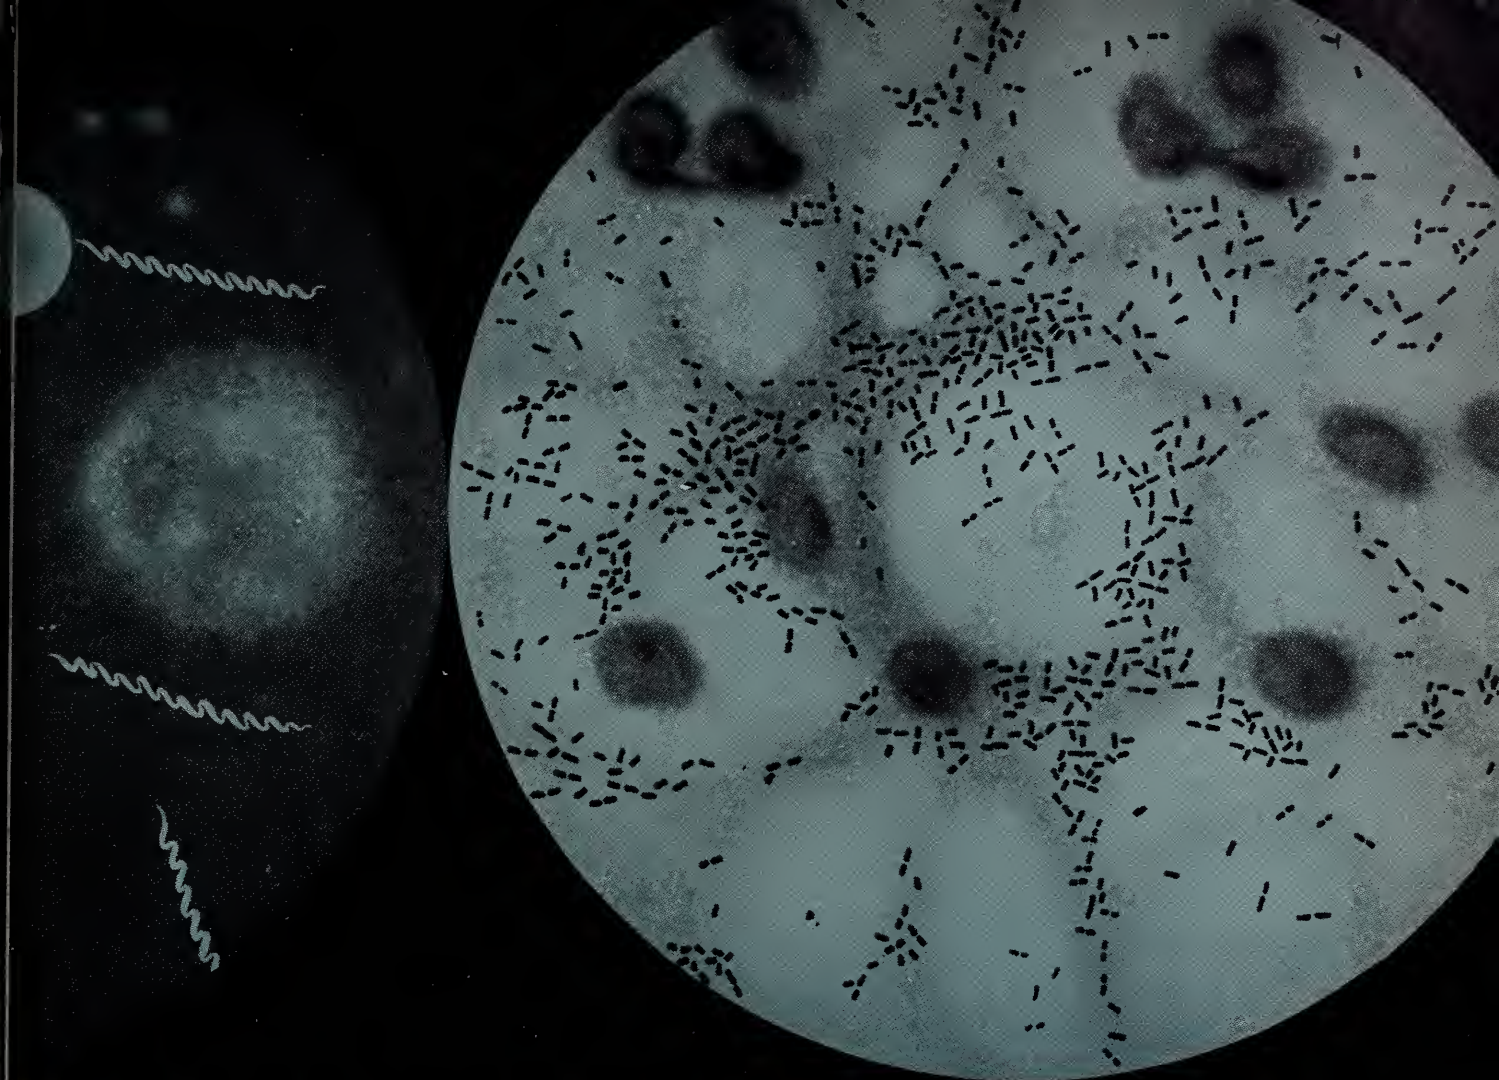
Dr. R. Shin, formerly of Grand Meadow, recently opened offices in Howard Lake. Doctor Shin's office i in the same building that was occupied by **Dr. Thoma** of Howard Lake.

* * *

The Twin City Society of Pathologists was recently formally organized with the adoption of a Constitution and ByLaws at a meeting held on February 4, 1960. The purpose of this society is to advance the quality and knowledge of pathologists in the Minneapolis-St. Paul area, and to co-operate with state, national and international organizations of pathologists in maintaining the high standards of pathologists. The following officers were elected: president, **Dr. C. W. Freeman,** Minneapolis; vice president, **Dr. Wayne Chadbourn,** Minneapolis; president-elect, **Dr. Walter Subby,** Wayzata, and secretary-treasurer, **Dr. E. A. Hanske,** Minneapolis.

Nation's Leading Designers and Builders of prefab "Medical Buildings"

An Erdman prefabricated medical building



• *designed to insure efficiency*

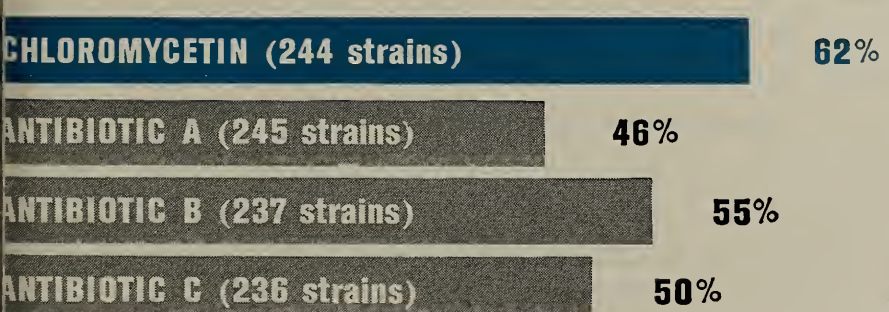
An efficient suite for medical use is not just a group of rooms. It has to be engineered to make the best use of space. Erdman prefabricated medical offices are individually designed for the selected building site and with your specific needs in mind, just as we have done for more than 275 doctors throughout the country.

• *prefabricated to save money*

Because of standardized plans, mass-produced parts and materials, and experienced craftsmen — Erdman saves much in costs, minimizes construction time and insures an ideal building.

If you are interested in a medical building, write Marshall Erdman and Associates, Inc., 5117 University Ave., Madison 5, Wisconsin.

CHLOROMYCETIN®



UTSTANDINGLY EFFECTIVE AGAINST A WIDE RANGE OF PATHOGENS

LOROMYCETIN (chloramphenicol, Parke-Davis) is available in a variety of forms, including Kapseals® of 250 mg., in ttles of 16 and 100.

LOROMYCETIN is a potent therapeutic agent and, because certain blood dyscrasias have been associated with its admin-ration, it should not be used indiscriminately or for minor infections. Furthermore, as with certain other drugs, equate blood studies should be made when the patient requires prolonged or intermittent therapy.

GENERAL INFORMATION

Authors

Manuscripts should be addressed to Arthur H. Wells, M.D., Editor, 915 East First Street, Duluth 5, Minnesota. Telephone RA 7-6636 or JA 5-2319. Original papers prepared for publication solely in Minnesota Medicine will be considered by the Board of Editors providing they fulfill the following editorial standards. Manuscripts should be typed double spaced on white paper with at least 1-inch margins. The original (not a carbon copy) is requested. The title on the first page should be under six words if possible or divided into two parts. The author should give his highest degree, his institutional position or his relationship to a hospital or medical organization which he may be addressing. Pages should be numbered consecutively and the author's last name should appear at the top of each page.

Bibliographical references should appear on a separate sheet entitled References. They should appear and be numbered consecutively in the order in which they first occur in the text (not alphabetically). Citations in the text require reference numbers if the author's or authors' names are not used or if there is more than one reference to the same author or group of authors. All references to author should appear in the list of References and no references should be included which are not in the text. The style and exact punctuation used in the J.A.M.A. references are requested. Journal references should include: *Author's last name, initial., initial.: title of paper. Abbreviated name of journal, volume number: page, year.* Book references should give author, title, edition number, city, publisher and year.

Illustrations (photographs, tables and graphs) should be submitted separately and not combined in the text. There should be a separate sheet entitled "Illustrations" which contains the various types of illustrations listed separately and numbered in the order in which they appear in the text. All photographs must be in black and white, clear cut, contrasting, and on glossy stock. Instructions for combining photographs are acceptable. Any number of illustrations over 4 are charged to the author. Combinations of photographs up to one-half page (6 x 4⅜ inches) count as 1 illustration.

Readers and Reviewers

The right is reserved to reject material submitted for reading or advertising columns. The views expressed in this journal do not necessarily represent those of the Minnesota State Medical Association or any of its constituents.

Advertisers and Subscribers

Classified advertising—15 cents a word; minimum charge $3.00; key number, 25c additional. Remittance should accompany order. Display advertising rates on request.

Annual Subscription—$5.00. Single copies—$0.50. Foreign and Canadian—$5.50.

Communications concerning advertising and subscriptions should be addressed to Minnesota Medicine, 2642 University Avenue, Saint Paul 14, Minnesota. Telephone Midway 6-2641.

Cutaneous Reactions to Cosmetics and Related Substances

Here is an article which is not only of interest to the physician, but also to his wife. This paper awakens one to the hazards of skin irritation that are encountered in the woman's cosmetic drawer. Since men are using more of these preparations, neither sex is spared the disability produced by some of these substances. With so many new products appearing on the market, it would appear that greater study is required before their release to the public.

CARL W. LAYMON, M.D.
Minneapolis, Minnesota

From the Department of Dermatology, Minneapolis General Hospital, Carl W. Laymon, M.D., Director; and the Division of Dermatology, University of Minnesota, Francis W. Lynch, M.D., Director.
Presented at a postgraduate course for pharmacists, University of Minnesota, February 3, 1959.

COSMETICS, in all probability, would be used by fewer people if the possible risks of cutaneous reaction were known. Knowledge, however, does not seem to inhibit the desire to appear more beautiful. It is surprising that there are so few harmful dermatologic effects considering the world wide use of these products.

Hair and Scalp

Permanent waving requires softening of the hair with an alkaline sulfide followed by heat setting and then rinsing, or a cold process with thioglycolate followed by an oxidizer. Cold wave chemicals are usually innocuous, the beauty operator standing greater hazard than her client. The possibility of allergic response to wetting agents and perfume ingredients always exists, as well as to the essential waving chemicals. Ammonium thioglycolate in the concentration advised for home waving is seldom harmful if used according to directions. If the softening solution is applied too long or too concentrated, the hair may break off producing temporary baldness even without dermatitis followed by normal regrowth. Sataloff and Wilson (1951)[1] reported that a permanent wave solution ran into an ear canal and perforated the drum. Increase of education and regulations for operators of barber and beauty shops has minimized the dangers for the patrons but has not helped the operators. The dangerous agents may be classed as mechanical or chemical. The use of metal clips, plastic combs and brushes tends to break the hair. Metal may cause dermatitis, especially in the occipital area. As regards the chemicals, most of the dangerous or irritating ones have been removed by the industry but it is impossible to remove all of the sensitizing substances. Both thioglycerol and ammonium thioglycolate, which are used in cold waving processes, have an irritating plus a sensitizing action. Thioglycerol is a more potent sensitizer than ammonium thioglycolate.

Hair lacquers for upsweep coiffures may cause dermatitis of the ears, neck and eyelids. Howell (1943)[2] reported twenty-one cases of dermatitis due to hair lacquer within a few weeks. Most of

these women used lacquer pads. Most of Howell's patients, when patch tested, were found sensitive to only one brand of hair lacquer. Several of the patients who developed dermatitis due to the pads had used liquid hair lacquer for several years. Schwartz (1943)[3] reported that the irritant agent in lacquer pads was a synthetic resin made from a combination of resin and fumaric acid. These are the same compounds which are used in ordinary shellac.

Hair dyeing with synthetic organic dyes of the paraphenylenediamine group was apparently discovered about 1880 according to Thomas (1950).[4] This group of chemicals contains potent sensitizers. Sensitization is slow to develop and patch tests should be performed prior to each application even in persons who have not previously reacted. Hair dyes have produced much less dermatitis since 1937 than before that time because of improvements in their manufacture, the prophetic patch tests and instructions on the packaging requesting predyeing open patch testing regulated by law. The modern paraphenylenediamine dyes are not unduly hazardous. Many cases of dermatitis of the scalp, face, ears and neck have been reported, however, due to these dyes. The use of them in dyeing eyelashes and eyebrows has occasionally resulted in extremely severe dermatitis with eye involvement, which in a few cases has led to complete blindness. An eyelid cosmetic known as "Lash Lure" caused many cases of dermatitis several years ago. The dyes in certain lipsticks have been known to cause cheilitis.

Hair bleaches, usually containing ammonia and peroxide, have produced primary chemical irritation as well as sensitization dermatitis. Chemical burns from hair straighteners usually cause areas of complete depigmentation. This is most commonly seen in colored people.

The sensitizers in scalp cosmetics are numerous —the essential oils of bay rum, the synthetic perfumes of brilliantine and the various oils and gum resins in hair creams and curling applications. The many scalp lotions and tonics, despite ridicule, are still popular with the male sex. They contain irritants and sensitizers, for example, pilocarpine, cantharides, quinine, acetic acid, camphor, capsicum, betanaphthol, resorcinol, chlorohydrate, rose mary oil, bergamot oil and numerous other essential oils and chemicals. Shampoos have a tremendous popularity and contain perfume and sulfonated mixtures which may sensitize a susceptible person. The coconut oil shampoos are perfumed with several stable and synthetic and essential oils. Recently a medicated shampoo containing selenium sulfide enjoyed tremendous popularity and has been widely prescribed by physicians for seborrheic dermatitis. Grover (1956)[5] reported diffuse hair loss associated with the use of this product in six women. All of the women had used the shampoo at one- to four-week intervals for varying periods. Hair loss could not be correlated with administration of any other local or systemic medication. In all cases the hair loss stopped within a week or two after the use of the shampoo was discontinued. Grover thought that the falling hair in these women represented toxic effects of absorption of the selenium ion. An analogy was drawn with the hair loss in livestock with chronic selenium intoxication.

It should be noted also that hair oils and greasy pomades can cause aggravation of acne vulgaris and seborrheic dermatitis of the face. The same holds true for greasy applications applied directly to the face such as "make-up bases."

Face

The same remarks concerning oils, tonics, creams, lotions and pomades used on the scalp also apply to similar preparations applied to the face. Time does not permit mentioning the innumerable sensitizers which are contained in these cosmetics. In addition to the other preparations, liquid and cake rouge and face powder must be added to the list of possible causes of dermatitis.

Perhaps the use of so-called hormone creams containing estrogenic substances should be mentioned. There is no scientific evidence that the use of estrogenic creams will prevent the natural aging of the skin, let alone produce any type of rejuvenation.

Some perfumes and cologne waters contain essential oils which lead to photosensitization. Women usually apply these cosmetics behind the ears and on the sides of the neck, and following exposure to actinic rays a dermatitis develops on the area where the perfume or toilet water has been applied. After the active dermatitis subsides there may be persistent pigmentation.

Dermatitis of the face may be due to nail polish. The eyelids, chin and sides of the neck are the areas which are usually involved. Syn-

thetic formaldehyde sulfonamide resins are potent sensitizers and are the excitants of the eruption. Nail lacquer dermatitis rarely affects the hands. Involvement of the vulva and perianal region, however, is possible in a person who is sensitive to nail lacquer. A patient with any pruritic dermatosis is well advised to omit nail lacquer until her skin is clear, for where she itches she will scratch and where she scratches she will develop the dermatitis as a complication. Group sensitization to the chemicals in nail lacquer is frequent and people who have nail polish dermatitis may be sensitive to sulfonamides and formaldehyde.

Hands

Soaps are alkaline to a greater or lesser degree and are defatting agents, lacking which capacity they could not cleanse. Skins are variable with respect to the amount of soap usage they can withstand. Hands that may be soaped twenty times a day in the warm summer time may tolerate only half a dozen washings in the winter when the air is dry, the skin cool and the sebaceous secretions diminished. Soaps and detergents are frequently the inciting cause of dermatitis of the hands. A skin which is already inflamed tolerates soap poorly. Any soap contains many ingredients, each one of which may be irritating or sensitizing. Many a patient imagines that water alone is the cause of her soap trouble. As Sutton (1956)[6] aptly stated, however, about three-quarters of the human body is water and a person intolerant of water would indeed be in trouble. Superfatted soaps, of which there are many on the market, may be of some value in lowering the defatting capacity for these cleansing agents.

Several years ago base coats for finger nails which contained phenolformaldehyde resins and synthetic rubber in methylethyl ketone caused hypertrophy of the nail bed and onycholysis without indications of inflammation. These products, however, have been removed from the market. Allergy did not seem to be the explanation of these changes.

Sunburn Preventatives and Substances Used to Enhance Suntan

It is well known that persons differ in susceptibility to active rays, blondes being especially sensitive. There are many sun filters on the market. Dark red petrolatum was used in the Armed Services for flyers in the Pacific Area. It was effective. Paraminobenzoic acid (15 per cent) is said to protect against rays of 2900 to 3100 Angstrom units. Å-Fil, a proprietary manufactured by the Texas Pharmacal Company, contains 5 per cent each of menthyl anthralinate and titanium dioxide. It is a good sun screen. Tannic acid has also been used. Neo-Å-Fil (Texas Pharmacal Company) contains 3 per cent digalloyltrioleate in a vanishing cream base. It is said to block completely solar radiation from 2900 to 3150 Angstrom units. Some of the agents incorporated in sun screen products may produce photosensitization. Contact dermatitis can result from any one or a combination of the chemicals contained in these preparations.

The antihistaminic drug, Pyribenzamine, is said to inhibit sunburn because the absorption curve of the chemical has a high extinction peak in the erythemogenic part of the spectrum. This was shown by Kline and Baer (1948).[7] The antimalarial drugs, especially atrabine and chloroquin have been used in the treatment of lupus erythematosus and various eruptions associated with hypersensitivity to actinic rays. The effect is believed due to the ability of these substances to restore the adaptability of the skin to ultraviolet radiation. There is increasing experimental evidence that chloroquin not only reduces ultraviolet erythema but certain other inflammatory reactions in the skin as well. Also to be considered as an effective contributing factor in reducing cutaneous reaction to ultraviolet light is the thickening of the stratum corneum. Cahn and his co-workers (1954)[8] suggested, on the basis of their studies, that chloroquin produces its effects by modifying the reaction of the patient, so that abnormal responses to ultraviolet light are suppressed but not the normal ones. The work of Cahn et al adds evidence that a seemingly obvious explanation is not correct; that is, that deposition of antimalarial drugs in the upper layers of the skin acts to filter out the effective rays of ultraviolet light. These drugs, however, are not to be recommended to patients for obtaining a better suntan.

Following the introduction of psoralens into this country for the treatment of vitiligo, there was an observed increased melanin pigmentation and tolerance to sunlight in the nondiseased areas of some patients with vitiligo who were taking this drug and exposing themselves to sunlight. This led to preliminary trials of the preparation

in subjects with tendency to sunburn before tanning. Enthusiastic testimonial evidence was rapidly obtained from users of the material who claimed reduced sunburn and increased tanning. Laboratory and field trials indicated that pigmentation responses to sun could be augmented in human subjects with either topical or oral use of the psoralens. That tolerance to sun and capacity to develop a healthy looking tan are associated with various value systems in our culture is confirmed by the many letters received from patients pleading for increased tolerance or a better tan. Daniels (1958)[9] and his co-workers undertook a double blind control study of burning and tanning effects of the drug. Ten mg. of methoxyline was taken two hours before exposure to sun. The results were compared to the reactions in patients who took a mild sugar placebo. After taking the placebos some of the patients stated: "Tanner than ever before," "Stayed out whole days without burning," "Increasing exposure and increasing drug dose without any effect except more tan and no burn—wonderful." The study was not made in order to discredit the fact that methoxyline is a known potent photodynamic agent and the authors did not claim that the patients were reacting falsely to an inactive agent. They merely wanted to show that the testimonial type of data has a high inherent error. Arnold Jr. (1957)[10] also studied the psoralens and suntan. He found that the psoralens augmented sunburn response, shortened the time required for production and, other things being equal, increased its intensity and duration. The tan acquired may be of slightly different color or quality and perhaps more persistent than ordinary tan. He thought that the psoralens were valuable as agents to facilitate suntanning. He did not recommend their general use, however, and thought that they should be used only in a limited, closely supervised, experimental way in patients intelligent enough to be trusted with them. He also brought out the possibility that drugs which increase protective responses to light might also increase the carciogenic response. There has been insufficient time and study to decide this possibility.

Deodorants and Depilatories

The most common and distressing of the localized forms of hyperthrichosis is that which occurs on the face of women, with or without an associated excessive growth of hair on the arms, legs and chest. No internal treatment is effective in prophylaxis or cure. X-ray treatment is absolutely contraindicated. Temporary removal can be affected by shaving and by mechanical or chemical depilatories which are commercially available. The wax depilatories which mechanically remove the hair from the base of the shaft, and the corrosive ones, barium or calcium sulfide and the thioglycolates which destroy the exposed portions of the hair but do not penetrate far beneath the skin surface, are the ones used most commonly. These compounds can produce either folliculitis or contact dermatitis. Such irritations, however, must be extremely uncommon in view of the wide use which these products enjoy.

There are many different perfumes, waxes and astringent chemicals used in the multitude of deodorants which are on the market. Here too, contact dermatitis or folliculitis can result from these products. A new type of irritation in the axillas has been observed since stick deodorants came into extensive use. This manifests itself as a weeping, papular and extremely pruritic eruption with swelling, redness and burning. In these cases patch tests have been negative. Cosmetic companies have admitted that almost all of the stick deodorants contain sodium zirconium lactate. There have been many law suits as the result of eruptions developing from the stick deodorants.

In the management of cutaneous reactions to cosmetics, a sharply focused history is the most important in the search for possible causes. In many cases, the use of the patch test is an important aid. Patch testing, unless executed with knowledge and caution, however, may entail dangers. Many substances, if applied at the incorrect time, on the incorrect site, or in the incorrect concentration, or in the incorrect manner may produce both local and generalized reactions which can incapacitate the patient. For these reasons, it seems inadvisable to advocate the routine or extensive use of patch tests by the nonspecialist. It should be emphasized that the treatment of cutaneous reactions due to cosmetics and related substances requires scrupulous attention to detail on the part of the physician and the wholehearted cooperation on the part of the patient and of those who administer to the patient.

Subtotal Colectomy with Anal Ileostomy

A Two-Stage Procedure

SAM SCHNEIDER, M.D.
St. Louis, Missouri

From the Department of Surgery, Washington University, School of Medicine and the Divisions of Surgery, the Homer G. Phillips, the Veterans' Administration and the Jewish Hospitals, St. Louis, Missouri.

IN 1955, the authors[1] reported experiences with three one-stage subtotal colectomies with anal ileostomy as described by Ravitch.[2] Despite the long, stormy post-operative courses characterized by severe diarrhea, two of these cases were successful. The third patient developed a sloughing of the ileo-anal anastomosis necessitating eventual permanent abdominal ileostomy. This has been a common experience with such one-stage procedures. At that time a three-stage procedure aimed at circumventing these problems was introduced.

In 1957, the author[3] reported a two-stage procedure. The first stage consisted of a subtotal colectomy, pull-through anal ileostomy, and temporary proximal diversionary ileostomy. The anal-ileostomy was revised two days after the initial procedure. Three months after the initial surgery had elapsed, the patients had fully recovered, and the ileo-anal anastomosis had healed. If, at the end of this period, the patient was able to pass the continence test, an end-to-end ileo-ileostomy was performed.

This operation can be used in selected patients with ulcerative colitis. It can also be used in those cases of multiple polyposis of the colon with marked involvement of the terminal large bowel in whom one would ordinarily perform a total colectomy.

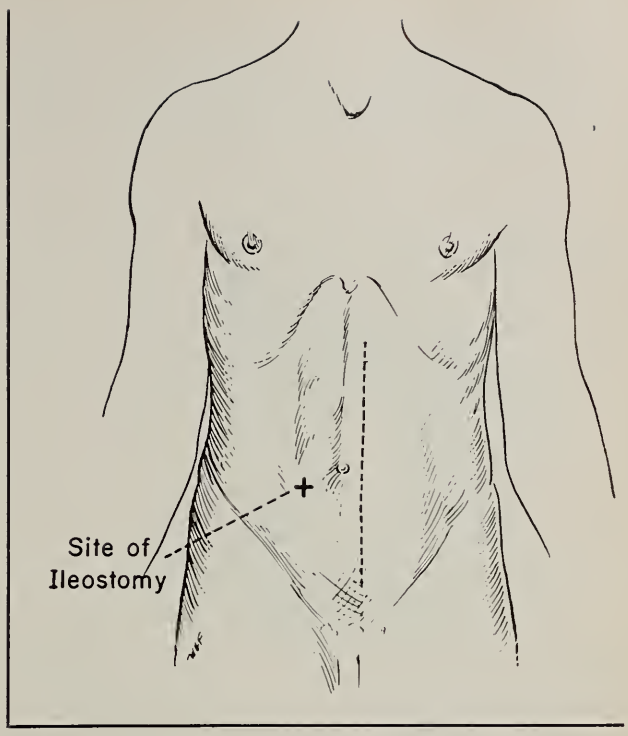

Fig. 1.

Presented as a colored motion picture with discussion before the St. Paul Surgical Society, September 16, 1959.

The illustrations, with some modifications, are from those appearing in AMA *Archives of Surgery*.

Operative Procedure

A Cantor tube is inserted prior to operation for long intestinal intubation to facilitate the surgery. With the patient in a supine position, the site of the ileostomy is marked. The patient is then placed in a lithotomy position and a long left paramedian incision is made (Fig. 1). This incision permits adequate exposure of the splenic flexure and pelvis, and leaves free the entire right lower quadrant for the site of the ileostomy.

The colon is completely mobilized before the mesenteric vessels are divided. However, when massive hemorrhage is the indication for colectomy, one should mobilize and section the blood supply to the colon starting in the right lower quadrant and proceding around to the left lower quadrant. To facilitate mobilization of the splenic flexure, the left half of the transverse colon is freed, and then the descending colon prior to mobilizing the splenic flexure.

The ileum is then transected near the cecum (Fig. 2). After occluding the colon about ten

inches proximal to the anus, the distal colon is irrigated thoroughly from below. Using a sponge forceps from below, a measured site approximately 4 inches proximal to the mucocutaneous junction is tagged, and the colon is transected at this location. If one preserves only the sphincters and their nerve supply, the patient will have sphincter control. For the patient to have continence also, however, it is necessary to preserve the muscularis and serosa of at least 2 to 3 inches of terminal large bowel together with its nerve supply.

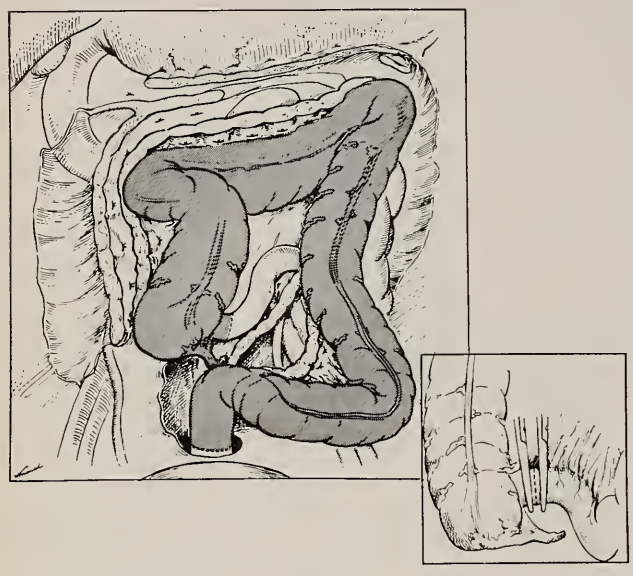

Fig. 2.

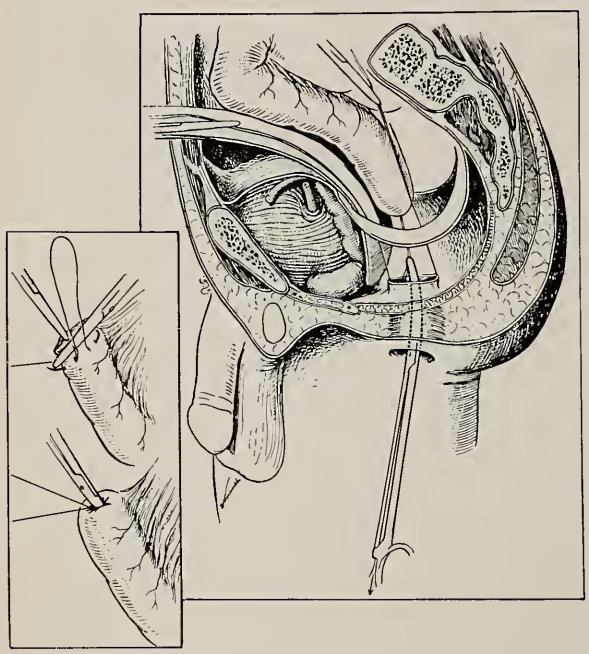

Fig. 3.

Curettage of the mucosa of the ano-rectal pouch is performed from below before transection of the colon distally. Sharp excision of the mucosa is inadvisable in patients with ulcerative colitis where scar formation makes such a procedure extremely difficult; on the other hand, excision of the mucosa is the method of choice in patients with multiple polyposis. In ulcerative colitis, it is unnecessary to remove all of the mucosa; in a patient in whom anal ileostomy was unsuccessful, an anal biopsy performed six months after colectomy revealed complete replacement of mucosa by granulation and fibrous tissue.

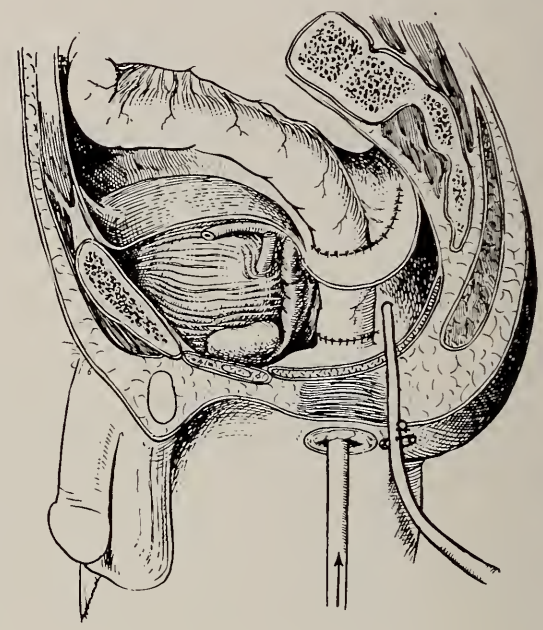

Fig. 4.

A simple purse-string suture is used to anchor the terminal ileum around a mushroom catheter prior to pull-through (Fig. 3). The catheter is inserted to prevent secretion of the ileum from bathing the terminal ileum when the latter is placed in the ano-rectal pouch. The terminal ileum is pulled through the ano-rectal pouch.

The ileum and its mesentery is sutured through the full-thickness of the proximal end of the ano-rectal cuff. The presacral space is drained lateral to the ano-rectal cuff through a lateral perineal stab wound as shown in Figure 4. The pelvic peritoneum is then sutured to the small bowel and to its mesentery.

The patient is now placed in a supine position. The ileum is transected with the precaution that

the segment to be defunctioned is sufficiently mobile for later re-anastomosis. The proximal functioning ileostomy is brought out through a right lower quadrant stab wound with excision of a small circle of skin. The mesentery of this segment is sutured to the anterior and right lateral parietal peritoneum to prevent internal herniation or prolapse. About 2 inches of ileum is

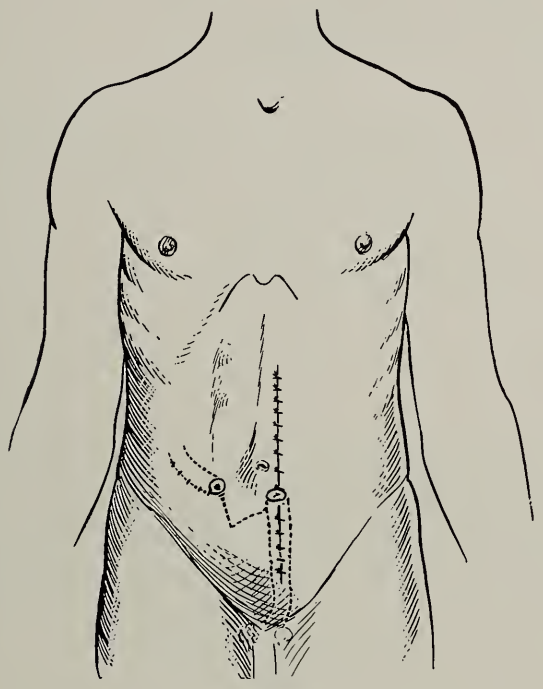

Fig. 5.

brought through the stab wound. The distal ileum is then folded back and the edge sutured to the edge of the skin with interrupted sutures. The proximal end of the defunctioned ileum is brought through the main wound (Fig. 5). The peritoneum and fascia are closed with figure 8 stainless steel wire sutures. The distal end of the defunctioned ileum is placed in the ano-rectal pouch.

Two days later the patient is again placed in either the lithotomy or the Sims position, and using local anesthesia, the perianal area and sphincters are anesthetized. A circular incision is made at the mucocutaneous junction of the anus. This incision is then undermined to expose the internal sphincter. After making certain that the ileum is under no tension, the serosa is sutured to the internal sphincter with fine sutures. The excess ileum is then transected leaving adequate length for suture to the perianal skin (Fig. 6).

About three months after the completion of the first stage the defunctioned segment is tested. A Foley catheter is used. The bag is inflated to occlude the proximal end of the defunctioned ileum. One hundred ml. of water is instilled into the ileum by way of the catheter. If this water is re-

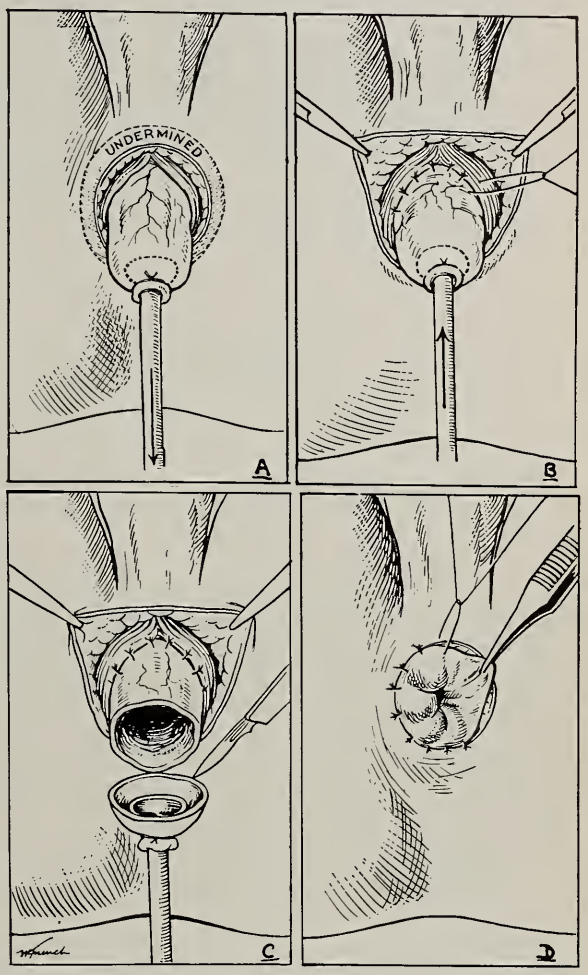

Fig. 6.

tained for four hours and then expelled, the patient has passed the continence test and is ready for ileo-ileostomy. The testing procedure should be repeated several times to insure adequate evaluation.

There are several excellent methods one can use to re-establish small intestinal continuity. We prefer the technique detailed in Figure 7. The left paramedian wound is reopened. The distal limb is mobilized. A transverse elliptical skin incision is made encircling the previously functioning ileostomy and the proximal limb mobilized. Fine silk or cotton is used throughout this procedure. First, a posterior row of interrupted seromuscular sutures is placed (Fig. 7A). This is followed by a row of posterior through-and-through interrupt-

ed sutures (B). The anterior opening is then closed by placing a row of inverting type of interrupted through-and-through sutures (C). Then an anterior row of sero-muscular interrupted sutures is used (D, E). After completion of the anastomosis the defect in the mesentery is closed. The right lower quadrant and left paramedian wounds are then closed.

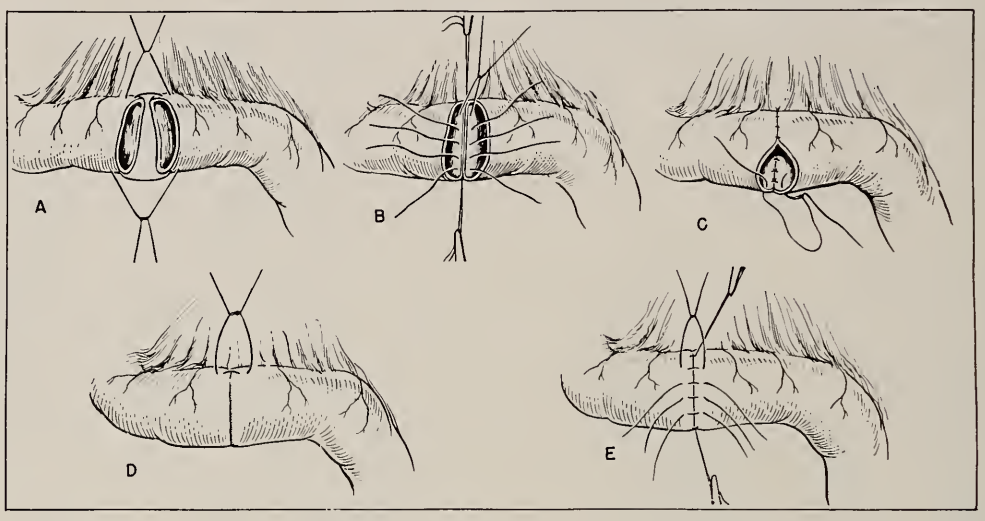

Fig. 7.

The shortest interval between the first stage and ileo-ileostomy has been two and one-half months, the longest two years.

Do's and Don'ts of the Procedure

1. Transect the ileum near the cecum to preserve maximum length of ileum and facilitate ileo-anal anastomosis *free of tension.*

2. Clamp the distal colon above the peritoneal reflection and irrigate the colon from below prior to curettage. This will minimize the possibility of presacral infection.

3. Drain the presacral space. Infection in this area may result in stricture and failure of the procedure.

4. Full thickness eversion of the temporary functioning abdominal ileostomy should be done. This prevents ileal dysfunction.

5. Don't attempt procedure if there is a short ileal mesentery. Some patients will not have a sufficient length of ileal mesentery to permit an anastomosis without tension; at present there is no way of lengthening this mesentery.

6. Don't attempt procedure in patients with previously destroyed sphincter mechanism. This is usually the result of excess scar formation in patients with fistulae-in-ano.

7. Do not attempt this procedure in patients with a recto-vaginal fistula. The induration and full thickness infection of the bowel in this condition diminishes chances of continence.

8. Do not attempt this procedure if there is gross disease of the terminal ileum. This indicates necessity for removing portion of ileum and possibility of further spread of disease.

9. Do not insert more than two and one-half inches of excess ileum into ano-rectal pouch in the first stage. The blood supply to all of ileum in the pouch may be compromised and the ileum may slough.

10. Do not attempt this procedure in elderly patients. Rehabilitation is difficult in this group.

Summary

A two-stage anal ileostomy procedure has been described which is useful for selected patients with ulcerative colitis or multiple polyposis with marked involvement of the distal large bowel.

The do's and don'ts of this procedure have also been presented.

Amblyopia

RICHARD O. LEAVENWORTH, JR., M.D.
Minneapolis, Minnesota

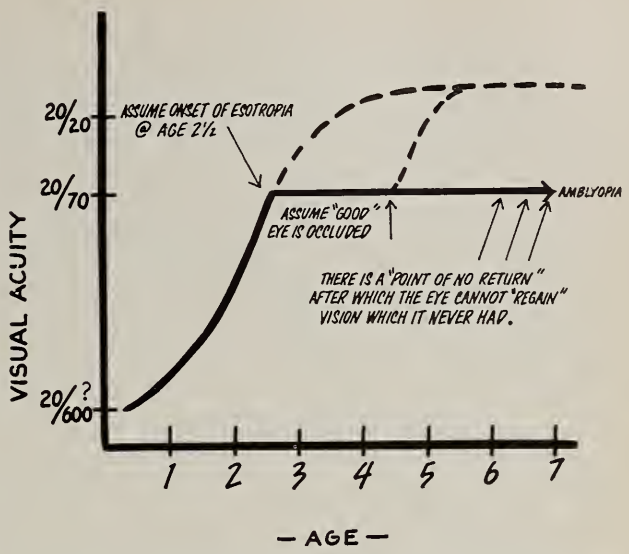

Fig. 2. Schematic demonstration of Amblyopia ex anopsia in a crossed eye.

A "lazy" or weak eye in a growing child must be detected and treated before age six to avoid permanent visual disability. It is difficult to impress some parents with this necessity and all physicians must be impressed with their sight-saving role.

From the Department of Ophthalmology, St. Louis Park Medical Center, Minneapolis, Minnesota.

IT IS EASY to demonstrate to parents our concern over their cross-eyed child's deviating eye. It is much more difficult to impress upon them the need for preventing the development of a "lazy" or weak eye in the growing child. Of the two problems, treatment of amblyopia is far more important than treatment of a squint. Indeed, in the treatment of a squint our attention is directed first to establishing good vision in each eye.

Amblyopia has been described by Duke-Elder as a situation where one eye can't see well, and you can't see why. A patient with poor vision in one eye, without significant refractive error, without disruption of the passage of light through the ocular "media" (that is, cornea, aqueous, pupil, lens and vitreous), and without evidence of disturbance of the retina or optic pathways, has amblyopia. More precisely amblyopia is a selective cortical suppression of "macular pattern vision." The term "macular pattern vision" is used since often a patient unable to read any of the letters in a complete line (such as the 20/40 line) is able to read single letters of the same size.

Amblyopia is a common disorder. Dowing[1] found an incidence of 3.2 per cent in 60,000 Minnesota W. W. II selectees. A more recent study revealed a 5.27 per cent incidence among the general population.[2] Amblyopia can easily be detected, and can be positively diagnosed. Amblyopia is easily corrected, but only if treated early (before the age of six).

Detection

Suspect amblyopia whenever the two eyes show different levels of visual acuity. Establish the diagnosis by failure to improve the faulty eye's vision by appropriate glasses, and by ruling out intraocular pathology (such as cataract, macular disease, et cetera).

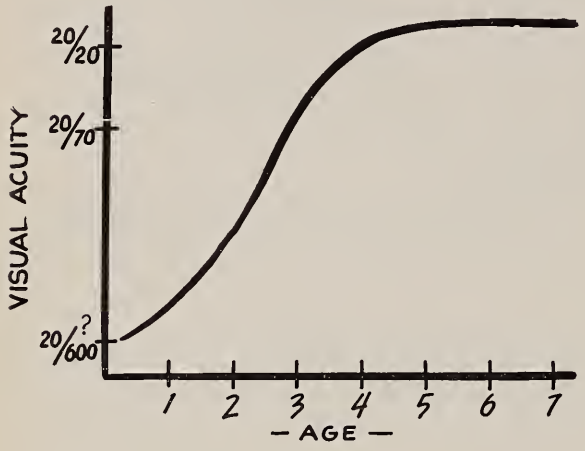

Fig. 1. Normal development of central visual acuity according to the theory of Amblyopia ex anopsia.

Well-child examinations (aged three) and pre-school examinations (aged four to five) should include tests for amblyopia. Physicians who examine these young patients should have a nurse or other aid well trained in the use of the kindergarten or illiterate E charts,* and aware of the tricks a child will employ to "peek" through a supposedly covered eye. If a pre-school child is unable to co-operate for E-chart testing, a repeat visit after practice at home is mandatory.

Special vigilance is in order for any child with a squint. As part of his routine examination, the family physician or pediatrician should include the following two tests:

1. Examination of the corneal light reflexes for evidence of asymmetric centering of the otoscope light in the two pupils.

2. The cover test, to examine for eye movement on covering one eye and then the other.

Either test, if abnormal, demonstrates the presence of squint. Further details on these tests are well outlined in a recent article by McNeill.[3]

Etiology

Amblyopia is most commonly seen in one of two conditions; namely, squint (especially convergent squint) and anisometropia (unequal refractive error). The following are several examples.

1. Boy, aged sixteen, SLPMC No. 35507. The best corrected vision was OD = 20/20; OS = 20/80. The diagnosis was left esotropia and left amblyopia. This patient has a left esotropia of moderate degree, present since early childhood. The amblyopia reduces the chance of a successful cosmetic result. Binocular vision is lacking even if the eyes are straightened and thus the new position is less likely to "hold."

2. Man, aged forty-four, SLPMC No. 35904. The best corrected vision was OD = 20/20; OS = 20/50. This man gave a history of being cross-eyed as a child, but his eyes are now perfectly straight. He is a good example of the cross-eyed child who "grows out of it," but at the expense of good vision in one eye.

3. Girl, aged fourteen, SLPMC No. 55893. The best corrected vision was OD = 20/20; OS = 20/400. The diagnosis was anisometropia and amblyopia. Cycloplegic refraction in this girl revealed the following correction: OD = +.75 = 20/20; OS: + 5.00 = 20/400.

4. Girl, aged eight, SLPMC No. 35587. Presenting vision OD = 20/40; OS = 20/100. This child had been examined on three previous occasions by an optometrist, without treatment. Cycloplegic refraction revealed OD: + 2.00 + 2.25 cx 85 = 20/20; and OS: + 2.25 + 3.75 cx 95 = 20/40. This case illustrates the need for adequate refraction, with cycloplegia if necessary.

Theories of Development

There are two theories as to the development of amblyopia. The first is represented by the term amblyopia ex anopsia (poor vision from not seeing). The second is better described by use of the term suppression amblyopia.

Amblyopia ex anopsia suggests that the poor vision is the result of failure to use the eye, and thus implies a passive process. This theory assumes we are born with poor central visual acuity (for example 20/600), and that use of the eye is required to develop sharp vision (which is therefore a conditioned reflex).

*E charts and instructions on testing young children are available without charge from the Minnesota Society for the Prevention of Blindness, Palace Building, Minneapolis 1, Minnesota.

Suppression amblyopia implies an active inhibitory reflex rather than a disruption in the learning process of vision. There is an actual cortical suppression of the image from one eye to avoid confusion, and a foveal (mid-macular) scotoma is actually produced (Fig. 3).

Each theory has its strong advocates and each serves a useful purpose in the practical understanding of amblyopia.

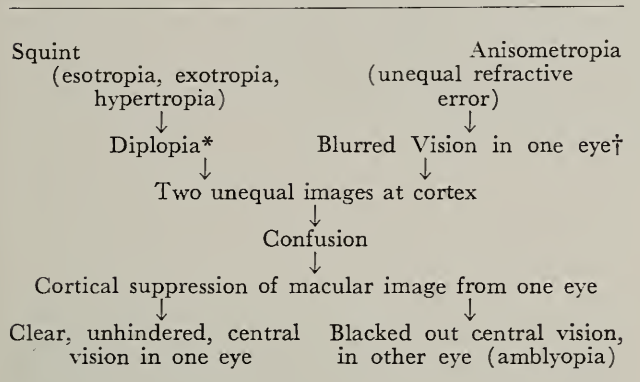

Fig. 3. Mechanism of production of amblyopia according to "suppression" theory.

*A startling illustration of the confusion produced by diplopia can be had by placing a 4 diopter prism base up before one eye.

†A similar illustration can be obtained by placing a +3.00 lens before one eye.

Treatment

The first step in treatment is correction of any significant refractive error. Then, total and constant occlusion of the non-amblyopic eye is necessary to:

1. Allow further development of central visual acuity in its previously interrupted learning process, or

2. Allow the central scotoma to recede, and fixation to return to the fovea where maximum visual acuity exists.

Take your choice of these two theories—the treatment is the same.

Partial (part of the day or week) occlusion is of questionable value in my experience. I often recommend that patients leave the patch on all night to avoid that half-hour lapse in the morning before the cover is re-applied. Examination for improvement in vision should be made about every three weeks, and occlusion should be continued up to three months or longer.

TABLE I. RELATION OF IMPROVEMENT IN AMBLYOPIA TO AGE AT ONSET OF TREATMENT

Number	Pathology	Age First Occluded (yrs.-mos.)	Initial Corrected Vision	Final Corrected Vision
1	ET	3-7	20/80	20/20
2	ET	3-9	20/200	20/20
3	ET	3-9	20/200	20/25
4	XT	4-3	20/40	20/20
5	ET	4-10	20/400	20/20
6	ET	4-11	20/400	20/20
7	ET	5-4	20/70	20/20
8	R ≠ L	5-9	20/30	20/20
9	ET	6-0	20/60	20/20
10	ET	6-3	20/50	20/20
11	R ≠ L	6-5	20/30	20/30
12	R ≠ L	6-7	20/50	20/40
13	ET	6-8	20/40	20/20
14	ET	6-9	20/50	20/25
15	ET	6-9	20/300	20/40
16	ET	6-11	20/30	20/20
17	ET	7-5	20/30	20/30
18	ET	7-10	20/200	20/50
19	R ≠ L	9-3	20/60	20/25

ET=Esotropia (Convergent squint)
XT=Exotropia (Divergent squint)
R ≠ L = Anisometropia (Unequal refractive error)

Results of Treatment

In youngsters under the age of six years, improvement to 20/20 vision can be expected in almost every case. However, in patients over age six and one-half years, results are generally more disappointing. In Table I, patients are arranged in order of age at onset of occlusion, and improvement in visual acuity is recorded in the right hand column. Occlusion was continued in each case, until no further improvement occurred after an additional three weeks of treatment. The final vision in the first ten patients ranging from three years, seven months to six years, was 20/20 in all but one. In the remaining nine patients, occlusion was started after age six years and the final corrected vision usually fell short of 20/20 acuity. This experience is well known to all ophthalmologists, nevertheless the evidence presents a strong argument for adequate screening for amblyopia in pre-school children.

Conclusions

1. Amblyopia is a threat to useful vision.
2. The need for detection and treatment prior to age six years is demonstrated.

Unexpected Sudden Natural Deaths

Unexpected sudden natural death is fortunately infrequent. Every physician needs to be familiar with its more common, although obscure mechanisms. Only by being armed with knowledge of its causes, together with pharmacological and mechanical skills for resuscitation, can the physician rescue more patients.

"Since every man who lives is born to die,
And none can boast sincere felicity,
With equal mind, what happens let us bear,
Nor joy nor grieve too much for things beyond our care,
Like pilgrims, to th' appointed place we tend;
The world's an inn, and death the journey's end."[1]

"Sudden death may be said to be a relatively rapid transition within minutes to a few hours from a state of comparative good health to the deceased state."[2]

"Unexpectedness outweighs suddenness, and this unexpectedness arouses a suspicion of violence. Unexpectedness means that this death may not have been foreseen a few hours previously and that deceased probably had a pre-existent organic disease of which neither he nor his relatives were aware."[3]

"15 to 20 per cent of all deaths are unexpected."[4]

"In a locality where sudden deaths are habitually reported due to disease, (without autopsy), a significant number are homicides, suicides or accidental deaths."[5]

"In those states having adequate laws, 20 per cent of all deaths need some investigation."[6]

"Death occurred so suddenly and unexpectedly that there was little or no opportunity to make an antemortem diagnosis. Often, and frequently erroneously, death is called sudden if the person is found unexpectedly dead as the result of natural causes, but the duration of symptoms is unknown."[7]

"The coroner's chief duty is to exclude death by violence or foul play and to recognize those due to natural causes, which, incidentally, constitute two-thirds of all unexpected deaths."[8]

"The coroner must exclude violence or foul play as a cause of death, they being found in one-third of the cases he investigates."[8]

IN THIS PRESENTATION, I shall omit reference to deaths from violence, homicide, suicide, automobile casualties and other accidents, and sudden deaths in early infancy (Table I).

Natural deaths must be differentiated from deaths by violence. "Many apparently dead from natural causes, even in the absence of external evidence of injury—actually were killed by violent means."[9]

Why should this subject be presented? It appears to me that there is a definitive need for acquiring and disseminating information regarding this matter because:

1. Comparatively little has been written and printed on this topic.

2. This type of death is infrequently witnessed.

3. By further study and research, valuable information may be obtained which could serve to prevent episodes of syncope and the like which

may lead to death and which also could disseminate facts and knowledge regarding resuscitative measures.

4. It is of fundamental importance medicolegally to establish the diagnosis of the cause of death—in order to detect crime and conversely to protect the innocent.

What is our philsophy of death? Death comes at the end of a long or short illness. It is said that there is no difference between death from accident and death from illness. "Instant death occurs only in cases of nerve lesions, but sudden death may be due to many causes."[10]

"Senescence is not an explanation of death—the cause being arterial degeneration, the ultimate cause is not known and there is no known preventative of such a lethal disease, namely arteriosclerosis."[10] Julius Caesar, being asked as to the most desirable manner of dying replied, "That form which is not anticipated."

Someone asked Axel Munthe what he regarded as life's greatest boon and he replied, "Sudden death with no doctors around."[11] There are a few articles in literature on the subject of dying, including Osler's essay which is well worth reading.[12]

Society demands that every sudden, unexpected and obscure death be fully investigated to determine its cause, for obvious reasons.

On investigation of the literature of the past ten years, it will be observed that various writers have different ways of classifying the common causes of unexpected death in the order of their importance.

In summarizing the deaths in young soldiers, there are five categories:[13]

1. Heart disease
2. Intracranial hemorrhage
3. Meningococcemia
4. Miscellaneous causes such as respiratory tract infections.
5. Obscure causes with negative necroscopic findings comprising 10 per cent of all sudden nontraumatic deaths of apparently healthy young men.

Another listing:[15]

1. Most common natural cause of death is coronary artery disease.
2. Next most common: Rupture of a blood vessel with fatal hemorrhage.
3. Death due to overwhelming infectious disease, producing no recognizable symptoms until the final espisode.[14] Massive obstructive edema of larynx incident to what was thought to be a minor infection.

One view[16] of the common causes of sudden death is:

1. Coronary disease or myocardial infarction.
2. Ruptured aortic aneurysm.
3. Cerebrovascular incidents or episodes.
4. Massive pulmonary embolism.
5. Exsanguinating gastro-intestinal hemorrhage.

Another author[17] epitomizes:

1. Deaths whose pathogenesis may or may not be explained by necropsy.
2. Sudden unexpected deaths with clinical explanation and necroscopic confirmation. Examples: Subarachnoid hemorrhage, previously known aneurysm, pulmonary embolis, prior existing fibrillating heart.
3. Unexpected deaths unexplained by necroscopy; e.g., the unexpected demise of emotional shock, great fright. inhibition, parasympathetic death.

"Instantaneous death is usually cardiac and there is a close similarity between instant death and syncope; and instant death is fatal syncope."[18]

Stress, strain and disease develop a condition of hyperactivity of reflexes which explains why the effect of emotions or chemical stimuli on the heart and vessels is slight, and surgical manipulations of certain central nerve structures may be done with safety—but in a few cases, such stimulating procedures precipitate alarming seizures and death.

Ischemic myocardium with hyperactive vagal reflexes may kill instantly during strain of defacation. Incidentally, the statement that "Ventricular fibrillation is the underlying physiological state in the causation of instant death" is disputed. "Hyper-irritable myocardium of anoxia, possibly of infectious origin and hyperactive reflexes, singly or in combination, play an important role."[18]

Not too uncommon is a situation where:

1. History and investigation yields very little information.

2. Necroscopic findings are negative.

3. Microscopical, biological, chemical, toxicological tests are negative.

4. If then we eliminate concealed injury, e.g. fracture dislocation of the neck, we must conclude that death is functional.

Allergy is mentioned as a not too infrequent cause of sudden unexpected unanticipated death, but much work remains to be done on this topic.

Anesthetic deaths are dramatic, tragic, unexpected and, rare. Most anesthetic casualties occur where there is a very serious primary disease and seldom is death due primarily to the anesthetic substance itself or to presurgical procedures, including anesthetic drugs. Occasionally, it is due to bad administration or a bad combination of various anesthetic agents or to hypersensitivity to cocaine or its derivatives.

Three types of dying are listed:[19]

1. Death within seconds—all manifestations of life except warmth disappear, there being no sequence of events.

2. The last scene in minutes. The heart stops either in ventricular standstill or ventricular fibrillation. (This kind of death is common but as it comes unexpectedly, it is not clearly understood.)

3. Miscellaneous deaths which do not occur so much suddenly as unexpectedly. For example: cerebral hemorrhage, thrombosis, pulmonary emboli, shock, etc. Which patient is liable to what type of death? What are the prodromes? If more were known, prophylactic measures, cardiac resuscitation and other procedures could be instituted at the proper time perhaps.

In Ramsey County during a ten-year period from 1949 to 1959, there was a total of 36,806 deaths, or an average of 3,680 per year. Of these totals, the Coroner's Office handled 6,110, or an average of 611 deaths annually (16.5 per cent).

In 1949, there were eighty-nine necroscopies performed (14 per cent), and in 1959 there were 182 necroscopies performed (29 per cent). Each year there was a figure of 203 deaths from violence (33.3 per cent) and 408 natural deaths (66.6 per cent). (Table II)

Case Citations

Case 1.—Man, aged sixty-five. Hemorrhage from the esophageal varices.

Necroscopic Report.—Esophagus showed varices along lower half. There was erosion at the esophageal-gastric junction and this opened into one of the varices. Stomach was dilated with estimated 1500 cc. of blood. Small bowel and colon contained old blood.

Cause of Death.—(1) Ruptured esophageal varices; (2) cirrhosis; (3) pulmonary edema; (4) diabetes mellitus.

Case 2.—Male infant, aged 3, died at home. The child was apparently perfectly well. The father was unable to waken the boy and called the police. The coroner at scene ruled death natural.

Necroscopic Report.—There was 50 cc. straw-colored fluid in the pleural cavities. Lung surfaces were smooth with small dark hemorrhagic areas. Cut section indicated thin watery fluid, blood-tinged.

Cause of Death.—Bilateral bronchopneumonia.

Case 3.—Man, aged fifty-nine. Necroscopy was performed. While driving his car, he was seen to weave in his lane and then drive off and hit a tree. He died instantly.

Necroscopic Report.—Abdominal cavity showed large hematoma arising from around celiac axis, two fractured ribs which do not enter the pleural cavities. Lungs were normal with no evidence of congestion. The heart was moderately enlarged. Valves and myocardium were normal. Arch aorta was markedly sclerotic. Coronary vessels also were markedly sclerotic. Abdominal aorta was markedly sclerotic with large irregular rough patches of calcium. In the region of the right renal artery, one of these was torn loose with a small rupture through the aorta from which blood came.

Cause of Death.—Rupture of the abdominal aorta due to arteriosclerosis.

Case 4.—Man, aged eighty-two. Necroscopy was performed. He was brought to the hospital in a private car. He had not seen a doctor for four months.

Necroscopic Report.—The abdomen, with subcutaneous fat, was smooth. The peritoneal cavity contained 600 cc. bloody sero-sanguinous fluid. There was massive retroperitoneal hemorrhage from the region of the left kidney across the midline, pushing forward the ascending colon and cecum, extending up to the diaphragmatic surface and inferiorly into the pelvis. Thorax: right lung showed few adhesions. The right pleural cavity contained about 50 cc. yellowish fluid. The left lung showed many dense adhesions over the diaphragm and lateral surfaces of the lower lobe. Heart valves were normal. Coronaries showed a moderate degree of atheromatous plaqueing. The myocardium was normal. The liver showed a nutmeat appearance. Examination of the gall bladder, spleen, pancreas, adrenals, kidneys, bladder and prostate resulted in negative findings. The gastrointestinal tract showed nothing of note. The abdominal aorta showed the presence of an extremely large aneurysm, measuring 17.0 cm. in length from the bifurcation of the aorta proximally. At the superior aspect of the aneurysm, a large rent about 6.0 cm. long was seen.

Cause of Death.—Ruptured aneurysm in the abdominal aorta.

Case 5.—Man, aged forty. Wife found husband "cold" in bed and called police. Necroscopy was performed. The man had had a surgical gastric resection three years previously and was receiving a pension for gastric ulcers from U.S.V.A.

Necroscopic Report.—External examination gave negative findings. The skull when opened showed no abnormalities. Examination of the brain revealed no evidence of injury or hemorrhage. The pleura were normal. The left lung was normal. The right lung showed marked congestion in the lower and mid lobes. No gross evidence of pulmonary embolus was found. The perica dium contained about 1 ounce of clear fluid. The heart was normal. There was a slight amount of atherosclerosis at the base of the aorta. Coronaries were patent. The upper abdominal cavity was obliterated by adhesions. The upper two thirds of the intestines was dark with what appeared to be blood. The stomach was opened, showing the gastric mucosa was hypertrophied and hemorrhagic. Contents were about a cup of bloody fluid with no clots. The mucosa of jejunum was attached to the stomach, which was also hemorrhagic. No gross ulcerations were seen. The liver, gall bladder, and pancreas showed no abnormalities. Kidneys and pelvic organs were normal.

Cause of Death.—(1) Pulmonary congestion right lower lung, undetermined cause, (2) hemorrhagic gastritis.

Case 6.—Girl, aged fourteen. Following spontaneous subarachnoid hemorrhage at her home, natural death ensued. Necroscopy performed. The child had complained of severe headaches the previous week, but was perfectly well otherwise. She had no medical examination or care.

Necroscopic Report.—On opening the skull, there was a diffuse subarachnoid hemorrhage covering most of the surface of the brain but mostly in the right temporal region. A large clot was found at the base of the brain in the region of the medi-cerebral artery. No definite aneurysm was found. Vessels were frail and tore easily. There were no other abnormalities.

Cause of Death.—Subarachnoid hemorrhage (Dr. Sterner, pathologist).

Case 7.—Man, aged forty-seven. Subarachnoid hemorrhage. Necropsy was performed. The man was found alone lying on the floor of his home. Final episode—he fell on the floor. He was a tuberculous patient at Ancker Hospital from January 11, 1957 to April 18, 1958.

Necroscopic Report.—There was cyanosis over the entire body, when death took place a considerable time before being discovered. There was no evidence of injury. The skull was opened, but there was no sign of fracture. The entire surface of the brain was covered with hemorrhage. The circle of Willis was dissected out. The right chest pleural cavity was obliterated by adhesions; the left chest partially so. Coronaries showed

moderate atherosclerosis, especially in the anterior descending branch.

Cause of Death—Subarachnoid hemorrhage.

Case 8.—Woman, aged fifty-five. Necroscopy was performed. The woman, who had suffered a compound ankle fracture, was admitted to the hospital and died eight days later. While in the hospital, examination showed rales in the bases of both lungs, and chest radiograph showed haziness at the base of the left lung. There was a question of cardiac decompensation or pneumonitis. The terminal episode began with dyspneia, perspiring, and weak pulse. Blood pressure dropped from 140/72 to 102/60. The patient was given oxygen. There was cyanosis of the fingertips and epigastric distress.

Necroscopic Report.—The heart was normal. There was adrenal, moderate cortical atrophy. A fresh embolus in one artery measured 5 mm. in diameter. In another artery, there was a large 15 mm. fresh embolus.

Cause of Death.—Massive pulmonary embolism.

Case 9.—Man, aged thirty-nine. While sitting in a dentist chair, with dentist working on his teeth, this man suddenly died. He was previously well, and when questioned by the dentist as to his good health, all answers were normal. Blood pressure was normal. The dental assistant gave the anesthetic of nitrous oxide and oxygen, and three teeth were removed in one minute. The dentist observed a slight cyanosis, but no trouble in breathing. He ordered the anesthetist to increase the oxygen until the patient was receiving pure oxygen.

Necroscopic Report.—Cause of death was cardiac arrest and edemic congestion of the lungs.

Case 10.—A man, aged forty-nine, had been previously treated for cancer of the larynx. After being ill at home for a few hours, he was taken to Ancker Hospital, where he suddenly died.

Necroscopic Report.—Laryngectomy, old; brain atrophy, slight; pyelitis, slight.

Cause of Death.—Severe coronary sclerosis.

Summary

The literature for the past ten years has been reviewed and the categories of death as classified by different authors have been given. Unfortunately, not enough is presently known as to the details of the different methods and manners of dying. Further study and research along these lines has been suggested with a view toward increasing knowledge by more efficient and comprehensive post-mortem examinations. It has been suggested that this might even be life-saving.

A physician should become more familiar with the subject of dying and be especially concerned with sudden unexpected and obscure types of death. He should know the various procedures of resuscitation, the techniques of the proper use of drugs, methods of opening the chest and of cardiac massage and other relevant data and procedures.

Knowing these well, it would be logical to assume that he then may be able, if only on rare occasions, to restore life to one apparently dead.

The Dilemma of Dislocations of the Hip Following Dashboard Injuries

WALTER INDECK, M.D.
Minneapolis, Minnesota

Presented at the symposium on automobile trauma held at the Methodist Hospital, St. Louis Park, Minneapolis, Minnesota, November 14, 1959.

WITH THE advent of high speeds and an increase in auto accidents, dashboard injuries, dislocations of the hip and the dilemma of treatment has confronted the physician who treats injuries.

Of 661 automobile injuries reviewed in a series by Kulowski, fifty-five (10 per cent) involved the pelvic region. Almost twenty involved the hip joint proper with the predominant injury a fracture-dislocation. There were five fractures of the acetabular region without dislocation and three pure dislocations without fractures.[4]

Pathomechanics

Two main mechanisms of injury exist, usually dependent on whether the passenger remains with the car or is ejected.

When an occupant is thrown from the car, an impact against the outer aspect of the thigh may result in direct stress to the lateral thigh aspect with the stress subsequently transmitted through the head and neck region and finally to the acetabulum. This mechanism of injury will be discussed more completely under the subheading Central Dislocations of the Hip.

Following the knee-dashboard impact that results when the patient remains with the car, several bony areas successively receive the brunt of the stress. The pattern of force is transmitted from the patella to the femoral condyles, to the supracondylar region, to the intertrochanteric region and finally to the hip joint.

The sex of the passenger may determine the final disability. The usual position of the male in the front seat of an auto is one of wide abduction, whether he is the driver or a sleeping passenger. In this position, the femoral head is well seated in the acetabulum with the greater trochanter almost abutting on the posterior and inferior aspects of the ilium. With the continuing force of the stress in this abducted position, there is a central thrust and a large fragment of acetabulum is fractured. The usual position of the female is with the hips adducted or the legs crossed. The femoral head thus is well out of the acetabulum and posterior dislocation of the hip results from the impact. A smaller acetabular fragment may be created but large fragments and femoral shaft fractures are not as common as in the male.[6]

Anterior dislocations result from exaggerated abduction and external rotation. This mechanism is uncommon. The thrust is created from the momentum of the body as it continues forward while the knee becomes fixed against the dashboard or the legs braced against the floor. If there is any

backward inclination to the trunk, as is seen in a hyperextension position of the spine, then a large postero-superior wedge of the acetabulum may be sheared off.

Pathological Anatomy

The femoral head can be dislocated only if there has been extensive fraying of the ligamentum teres or if a complete tear has resulted. Anteriorly the ilio-femoral ligaments form a buttress to prevent dislocation, but posteriorly there are no significant ligamentous structures, and the acetabulum is shallower.

When the hip is dislocated posteriorly, the short rotators, gemelli and quadratus femoris are usually torn. In anterior dislocations, extensive tears of the rectus and adductor groups may result.

In respect to the periarticular structures when a large segment of the bone is detached from the rim, the capsule is essentially intact except for possibly a single tear in its posterior portion. The head does not protrude through the capsular and periarticular structures but presents between the fracture fragments.[9]

Osseous Structures

In respect to acetabular fractures, the subsequent classification as suggested by Bohler[1] is made to identify the extent of trauma:

Group I. Dislocations of the hip without fractures.

Group II. Dislocations of the hip with minor avulsions of the bone, secondary to ligamentous tears. These avulsions are usually seen at the superior or inferior lips. The reduction is stable if the fragment is not large enough to become interposed during the mechanism of reduction.

Group III. Dislocation plus posterior lip fragments which follow when slight abduction to the thigh had been present during the mechanism of injury. A stable joint is usually formed following reduction. Avascular necrosis is not common in the preceding three groups.

Group IV. Dislocation plus a large wedge created from the posterior-superior portion of the acetabular roof. Here the joint is usually unstable following reduction and there follows a relatively high percentage of avascular necrosis of the femoral head.

Group V. Dislocation with considerable disruption of the acetabular floor. The fragments are usually displaced medially and an unstable joint created.

Two degrees of obvious trauma may occur to the femoral head. Cartilaginous flakes and small fragments of bone from the femoral head may be formed by the initial injury or from the mechanism of reduction. Both foreign bodies may become manifest after several years as impinging elements during the range of motion and possibly perpetuate arthritic changes in the joint.

The subchondral area of the femoral head may become contused and crushed following impingement against the acetabalum. On x-ray these changes may not be readily seen because the over-all contour has been restored. The presence of a large acetabular fragment should arouse the suspicion of a serious contusion of the subchondral bone of the femoral head.

Marginal fractures may be detached but are usually insignificant in respect to over-all articular surface. The proximal femoral epiphysis may be displaced and simultaneously reduced when the dislocated hip is reduced. If an adequate reduction has not been obtained, surgical replacement is necessary. Fractures of the femoral neck and shaft may also occur with the dislocation.

Nerves

Following posterior dislocations the sciatic nerve may become interposed between the femoral head and acetabulum and block reduction. Prolonged pressure from displaced acetabular fragments may result in significant injury to the nerve. The femoral nerve is subject to pressure in anterior dislocations but this is a rare feature.

Arteries

The femoral artery is a potential source of disaster in anterior dislocations. No significant major vessels are compressed with posterior dislocations.

Clinical Examinations

The general appraisal of the individual following an accident must precede local evaluation. The presence of shock must be recognized and treated. Relatively normal blood pressure, pulse, and respiration may offer a false sense of security to the doctor. If these signs are taken at face value, the pale sweaty individual who is experiencing extreme pain may continue in shock.

Once the individual's general appraisal has been made local evaluation of pelvis and hips can be completed. A posterior dislocation of the hip is suggested by adduction, flexion and internal rotation of the lower extremity. An anterior dislocation is suggested by abduction to 60 or 70 degrees and the knee extended.

The color and temperature of the limb, the integrity of the dorsalis pedal and posterior tibial arteries, the patellar and Achilles reflexes can all be quickly determined and offer the necessary information in respect to distal neurovascular supply. Anti-shock measures should be instituted immediately, open wounds covered, and once the patient's condition stabilized, specific x-ray studies can be obtained.

Pain and shock may be intensified if the patient is moved before adequate, even though crude, splints are applied. The increased hazard of fat embolization following inadequate splinting is real.

X-rays are important in evaluating concomitant fractures or injuries, especially to the neck or trochanteric region of the femur. Specific attention must be paid to the over-all configuration of bone. In posterior dislocations, the lesser trochanter is rotated sufficiently so that it may not be visualized. In anterior dislocations, the lesser trochanter may be seen in profile while the greater trochanter lies behind the femoral head. If pelvic ring damage has been associated, the combined procedure of catheterization and cystogram may be accomplished to offer an early appraisal of urethral and bladder trauma.

Therapy

Following stabilization of the patient's condition and exclusion of other major significant injuries, the dislocation must now be treated. Depending on concomitant injuries and possibly the relationship of recent food ingestion to the time of injury, the choice of anesthesia may vary. Stuart and Milford stress the urgency of reduction because in their evaluation of forty patients following closed manipulation, none, in whom reduction was delayed beyond twenty-four hours, showed a good result. It is possible to accomplish a reduction with local infiltration of 2 per cent xylocaine but frequently enough spasm has occurred that the relaxation offered with spinal or general anesthesia is necessary.

Text books[3] frequently offer circumduction maneuver to reduce the dislocations, but the following maneuver is applicable to both anterior and posterior dislocations. The patient is placed in a supine position with the hip and knee flexed. The hamstrings become relaxed, a posterior dislocation placed at the level of the acetabulum from its superior position and an anterior dislocation converted to a posterior dislocation. With the pelvis then steadied by an assistant or a binder, longitudinal traction is applied to the lower extremity. It should not be necessary to rotate the femur, and circumduction may actually result in an acetabular lip fracture or further tear in the sciatic nerve.

Once reduction has been obtained, the rehabilitation program can be started. It is difficult to find a group of traumatic surgeons or orthopedists who will agree to a uniform plan. The following may be used as a working baseline. Balanced suspension traction of 5 to 10 pounds, for a four- to six-week period will allow soft tissues to heal adequately. In most cases, this weight is sufficient to overcome post-traumatic muscle spasm and pain. When pure dislocation exists without associated fracture of either the lip or the head, mobilization can then be started and a weight bearing regimen planned. Femoral head collapse and avascular necrosis do not occur as frequently in pure dislocations as when associated with gross fractures. Unsupported weight bearing in the extremity should be deferred for approximately four to six months, and an ischial seat long leg brace may be utilized for support during this period.

Dislocations of the Hip and Acetabular Fractures

If a circumduction maneuver is used in the reduction, it is possible for fragments of the posterior lip of the acetabulum to become interposed. These fragments remain attached to periosteum at the level of the hip and do not displace with the femoral head. Reduction can be accomplished in most cases as a pure dislocation, and if interposition results, surgery is indicated to remove the fragment and replace it if significant to alter joint stability. Usually one or two screws will suffice to maintain stable fixation following replacement of large fragments.

If dislocations occur with marginal head fragments, these usually remain extra-articular following reduction, and no immediate surgery is necessary. This type of trauma is usually indicative of moderate injury to the femoral head and reconstructive procedures may be necessary in the future.

The after-care of patients sustaining dislocations

and large acetabular fragments must be more cautiously proposed. When the femoral head has received such trauma, reconstruction becomes a problem and protection much more definite. If a large fragment has been reduced but not fixed, a plaster spica for six to eight weeks is sufficient. This is followed by mobilization. If the large fragment has been fixed, then the limb may be continued in traction, and an ischial seat long leg brace may be given for ambulation without stress of weight bearing.

The use of an ischial seat long leg brace is to be considered whenever the mechanism of injury may have caused strain on the femoral head. A period of six to nine months may be chosen as the arbitrary period of protection and during which the greatest percentage femoral head necroses first appear. It should be stressed that the protection of weight bearing by a brace may serve only as possible prophylaxis to further disintegration of the head. The use of the brace is not advocated to prevent or modify the course of an asceptic necrosis occurring in the femoral head.

Central Dislocations of the Hip

Two groups occur differing in mechanism, pathology and clinical course; when the femoral head is dislocated toward the center of the pelvis in relation to the intact acetabular roof, and when the head is displaced superiorly and medially with a large acetabular fragment.

In the first group, the mechanics of injury is usually secondary to a force directed medially from the greater trochanter. This mechanism may follow a passenger's fall onto his hip after being hurled from a vehicle.

The femoral head becomes compressed by the force when it is driven against the anterior part of the acetabulum, and although radiographic alterations may not be present, this force should be appreciated.

In the second group, the mechanism may result from a fall to the ground when the iliac crest is struck before the trochanter. The strong anterior ilium and anterior acetabular roof fracture forward leaving the femoral head in a displaced position with a medial and superior portion of the acetabular roof. The displacement is not secondary to thrust on the femoral head, and pressure necrosis is not as common.

The treatment of central fractures of the acetabulum become difficult to assess. Recently several authors have advocated the use of open reduction and internal fixation to align and retain position of the fragments. If a serious, and usually prolonged procedure is contra-indicated by the patient's condition, continuous traction through the supracondylar region or tibial tubercle may be effective in obtaining and maintaining satisfactory position and early functional results.

The after-care of the patient following healing of the fracture fragments, which usually takes between six and eight weeks, is similar to that followed in the rehabilitation program in pure dislocations.

Conclusion

A dislocation or fracture-dislocation of the hip occurs in moderate frequency following knee-dashboard impacts. By attempting to categorize the extent of injury, some element of prognosis can be made and a plan formulated for therapy. Prophylactic care appears to be one of the few aspects available to the physician in preventing the complications of the injury. Early reduction and protection of full weight bearing by use of the brace are advocated on this basis.

Diffuse Pulmonary Emphysema

A Study of Surgical Treatment

MURRAY N. ANDERSEN, M.D.
WILLIAM CHARDACK, M.D.
PAUL KENNEDY, M.D.
JEROME MAURIZI, M.D.

Buffalo, New York

DIFFUSE PULMONARY emphysema is one of the few diseases which have not yielded to the therapeutic advances of recent years. Since it is most commonly a disease of advanced age, the progressive increase in longevity has produced an ever-enlarging number of patients suffering from this condition. Medical therapy with bronchodilators, expectorants, et cetera, provides symptomatic relief in a certain percentage of cases, but it does nothing to improve the basic architectural abnormality.

The principal ventilatory difficulty is in the expiratory phase. In the attempt to open the bronchial airways, the patient tends to maintain his lungs in a hyper-inflated state and to do his breathing at the "top" of his tidal volume. As a result of the latter, there is a great increase in residual air and ventilatory dead space, and inefficient intrapulmonary mixing of air. Because of the lowered and flattened position of the diaphragms, the patient tends to expend a disproportionate amount of his breathing effort in thoracic expansion, an effortful and inefficient method as compared to diaphragmatic breathing.

Considering these factors, it seemed that the mechanical abnormality could be improved by surgically decreasing the size of the lungs. In this way, the diaphragms would be allowed to assume a more normally elevated position, the rib cage could resume its customary obliquity, and the augmented negative intrathoracic pressure would tend to hold open the bronchi, allowing easier expiration. This method has been proposed and used in a series of patients by Brantigan[1] with apparently good clinical results.

Method of Study and Therapy

A battery of cardiopulmonary studies is performed before and after surgery, recognizing the well known inability to accurately assess the value of a procedure by asking a patient "how he feels." These tests have included spirometry and bronchospirometry, determination of residual air, and cardiac catheterization with measurement of pulmonary artery pressure, arterial and venous oxygen saturation, and cardiac output at rest and with exercise. Recently, analysis of lung compliance has been included in this program.

From the Surgical Departments of the University of Buffalo School of Medicine and the E. J. Meyer Memorial Hospital and Veterans Administration Hospital, Buffalo, New York.
Dr. Andersen is a Markle Scholar in Medical Science.

Patients have been selected for treatment on the basis of a history of progressive pulmonary insufficiency, chest x-rays indicating diffuse bilateral emphysema, and pulmonary function studies confirming the diagnosis of obstructive impairment of ventilation. No patients have been rejected because of severity of disease and the procedure has been carried out only in patients in whom disability was well advanced. The maximum breathing capacity of those operated upon has ranged in the vicinity of 27 to 39 per cent of expected normal. It has been empirically thought that the procedure would offer most to the younger patients, although gross estimation of a patient's physiological age is more valuable in this respect than chronological age. The patients operated upon have ranged from thirty-nine to sixty-seven years in age, the youngest representing a "juvenile" form of this disease which is in all pathological and functional respects similar to that seen in more elderly patients.

The surgical technique is simple. Operation is carried out, or planned, for both lungs, the second side being done several months after the first. Through a small thoracotomy incision peripheral sections of all lobes are removed by a simple wedge technique, excising the tissues distal

to a long curved clamp, or series of clamps, and oversewing the cut edge. It has been our experience that the disease is almost never truly symmetrical and tends to be worse at the apex of the lung and at the peripheral edges of the lobes, and an attempt is made to resect the most involved portions. When blebs or cysts are present, these are also excised. This procedure is continued until by gross observation the lung appears to fit comfortably within the thoracic cage or until the surgeon has removed as much tissue as he feels is safe without danger of inordinate air leaks postoperatively. Only experience will provide judgment in the amount of lung tissue which can safely be removed. By crude estimation, it has been considered that as much as 30 to 40 per cent of the gross lung volume has been exercised. In the interest of "setting" the diaphragm at a high level for maximum excursion and to lessen the air leaks by allowing lung to come against parietal pleura, pneumoperitoneum has been used in several cases beginning immediately after operation. This is maintained until air leakage has stopped and the patient is active and ambulatory and then is allowed to absorb.

Results

Despite the extremely poor functional condition of these patients and their well known difficulties during other types of surgery, it has been our experience that the procedure has been surprisingly well tolerated. It is usual to find that immediately postoperatively the patient's ventilatory effort appears to be decreased and his dyspnea lessened. It has been usual to observe rather free leakage of air from the cut surface of the lung, despite attempts at meticulous over-sewing, but in no case has this persisted for longer than nine days. No complications directly attributable to surgery have been seen to date and there has been no instance of postoperative pulmonary insufficiency. This may be due to the fact that our series is small and chance has played a part.

Results to date have been encouraging. All patients have claimed substantial subjective improvement and have shown grossly observable benefit as indicated by ability to carry on increased activity without dyspnea. Subjective improvement has been considerably more striking after the first stage than after the second, but this is reasonable when one considers the extreme disability of these patients; the improvement resulting from the first operation has frequently restored them to a state of comfort with moderate activity, and the second operation cannot be expected to provide as noticeable additional relief.

Only preliminary impressions may be given from the functional studies performed on these patients since the series is still small and the final evaluation in some patients is not complete. A slight improvement has been seen in maximum breathing capacity and vital capacity. In most cases, this improvement has been inadequate to account for the subjective improvement claimed. However, as one might anticipate, there has been a substantial reduction in the residual air compartment and it is probable that this accounts for the evident clinical improvement. In the catheterization studies, it has been a consistent finding that even though the pulmonary artery pressure may be normal at rest, there is usually a marked increase in the pulse pressure and a moderate increase in the mean pressure with exercise. This increased pulmonary resistance may be related to an observed inability to increase the cardiac output in response to exercise (in many instances there is an actual decrease in cardiac output during exercise). No final catheterization studies have been done at a sufficient time after surgery to indicate whether these changes in pulmonary resistance will be improved by the procedure. One patient, whose condition had progressed to cor pulmonale with overt heart failure, was operated upon with considerable subjective improvement from a unilateral procedure, although the degree of heart failure has remained approximately the same. Whether ultimate benefit can be provided in such patients is questionable, and one of the objectives of the study program is the attempt to determine which patients will be improved by surgery.

It should be emphasized that, although the initial studies have been encouraging and the low mortality and evident subjective improvement have stimulated us to continue the study further, it is not recommended that this method be adopted as a therapeutic procedure, and that it should be performed with the clear understanding that it is being carried out on a trial basis.

Preventive Psychiatry—Present Status and Future

Here is a provocative presentation of the enigmatic. The concepts discussed should stimulate further fruitful study.

CARL P. MALMQUIST, M.D.
Minneapolis, Minnesota

Dr. Malmquist is Resident, Department of Psychiatry, University of Minnesota School of Medicine.

INCREASING concern, interest and publicity in the field of mental health frequently raises the question among physicians and personnel working in this field as to what we know about preventive psychiatry at this stage of development, or what can we do in the way of prophylaxis against mental illness. The first question to be raised, although there is no specific answer, is what is mental health? At the present time, mental health is merely a concept since no one has been able to limit it to an empirical experience; yet, the values attributable to this concept vary. Thus a society placing peace and equanimity as the highest good will define mental health as tranquility; thus there will be more tolerance for resignation, withdrawal and other schizoid variations. If it is believed that man's role is primarily to work and accomplish, the mentally healthy will exclude those not productive. Those who believe that the healthy person is one who enjoys himself would consider others not able to experience pleasure as sick. Others have believed that it is man's role in life to suffer and purge himself, and that this is why he was born; thus those who suffer least would be considered images of mental illness.[1] These attempts to attribute certain values to mental health concepts are mentioned in an effort to by-pass them since the cultural relativity and impasse reached in determining the "good" inevitably results in endless unanswerable questions about what the "good" is. It is possible for various criteria to be discussed in terms of psychological meanings, and the lessened significance of judging mental health by the value approach is seen if it is remembered that it is merely one of many goals existing simultaneously, and that it should not be the aim of preventive psychiatry to mold the future for all civilizations.[2]

Historically, "mental hygiene" was suggested by Adolf Meyer in referring to the theme of Clifford Beers in *The Mind That Found Itself,* but it was used previously by William James in a lecture at Cambridge on "The Gospel of Relaxation."[3] Each of these three men had in mind a different approach to mental hygiene, and this is still present in contemporary work in this area. At the present, the approach of Beers seems most archaic, for he considered mental hygiene analagous to hospital reform programs with almost no stress on preventive aspects. James believed mental hygiene to be a promotion of a program of mental well-being so man could live a fuller life, whereas Meyer believed it was not just improved treatment of those mentally ill or promoting mental health, but preventing mental illness that was the crux because "this is the only effective cure known." Dr. Meyer also pointed out the two great obstacles that faced

To be published in two sections, of which this is the first.

the development of a mental hygiene movement. First there was a dogmatism and attitude of proprietorship which could be found in the church, school and university faculty each of whom believed to hold the human part of human nature in its grasp by means of the "humanities" in contrast to merely "natural science," and each of whom claimed to know from tradition and revelation all that was worth knowing about man and life. Second and equally stultifying was the rigid professionalized dogmatism of medicine and natural science which represented a mechanistic materialism and elementalism, orthodox and extolled as long as it left the mind, soul and behavior to philosophy and religion.[4] Today one is not impressed so much by these attempts to restrict a mental health approach, except in a few cases of extremism or the unsophisticated. There is more of a demand put on this new field to bear the responsibility and take the blame for the gaps and deficits now existing, whether this be due to an abrogation from failure of the traditional approaches, or the success of the new approaches ready to incorporate in its new techniques whatever was useful in the former.

Anyone having to deal with preventive psychiatry cannot avoid facing the problem of what mental health is or is not. Apart from obvious extremes there is no agreement on what types of behavior should be considered sick, and anthropologists remind us that what is accepted in some cultures would be regarded as sick in our civilization, but further what would be accepted in one part of our own country would be sick in another part. The question also arises as to whether personality disorders and problems of delinquency should be classified with mental illness. Dr. Jahoda has raised many questions concerning the nature of mental health and many of the concepts discussed below are suggested by her analysis.[5] The first question that must be raised is whether mental health can be considered equivalent to the absence of mental disease. Those who object to such a proposition base their main argument on the fact that it does no good to define one concept in terms of another where the meaning of neither of them is clear. The opposite view would seem to be that which the majority of physicians hold from their patho-physiologic orientation. As Barton states, the physician "sees health as the objective in the prevention, cure or management of disease to the extent that he can help the individual avoid it, recover from it, or compensate for it," and "mental health above the mere absence of disabling illness has yet to be scientifically demonstrated."[6] Those who think of mental health in this manner usually lay stress on the biochemical-physiological prerequisites of behavior and think of restoring a homeostasis for organic and emotional behavior. Attempts to use normality as equivalent to mental health also run into difficulty as it is a well demonstrated fact historically and medically that normality may not be the status of the majority of a population. Any such statistical definition of mental health has to select a reference population which involves a non-statistical concept of health as in selecting a group one is considering its performance from a mental health viewpoint; even when a population is selected, the problem of weighing different psychologic functions according to mental health importance must somehow be decided upon.

Much effort, most of it fruitlessly, has been expended to define mental health in terms of happiness. The World Health Organization has defined mental health as a "state of well-being" without any further specificities as to what the latter is. Even men like Menninger and Ernest Jones have listed happiness as one of the criteria for mental health. "Let us define mental health as the adjustment of human beings to the world and to each other with a maximum of effectiveness and happiness,"[7] and, "We have to consider happiness the most important attribute of normality . . . not simply pleasure but the capacity for enjoyment with self-content."[8] The limitation in this approach is the realization that happiness is not dependent on only the individual since many environmental aspects creating unhappiness are beyond individual modification. Social conformity may put demands on a person inconsistent with his self-content, and he must then choose between mental health or conformity.

Many psychological criteria have been suggested for mental health and some of these will be briefly mentioned. The concept of self-realization or fulfillment is one of the most frequently mentioned approaches to positive mental health. It is phrased in many different ways by different writers from Freud's life instinct to Allport's growth motives.[9] One must evaluate the individual here relevant to his using his potential to the best advantage he is capable of, not merely in an intellectual sense but in terms of how a person is progressing toward his objectives in any sphere. By this it is not meant

to consider healthy those activities done to promulgate self-importance, and "in view of the huge importance of cognitive and esthetic satisfactions in civilized human beings, it is safe to say that routinized education and amusements can have a terrific effect in stunting the growth of healthy personalities."[10] Another closely related concept of mental health is in terms of the individual's attitude toward himself usually described as self-acceptance, self-reliance or self-confidence. This takes in various meanings from ease of accessibility of the self to consciousness, objectivity to make a detached evaluation of oneself, and "accepting oneself" as one objectively is (not implying the negation of striving aspects). Jones has described this in terms of fearlessness, "but we must be clear that we mean by this not merely manifest courage, but the absence of all the deep reactions that mask unconscious apprehensiveness. Where these are absent, we have the willing or even joyful acceptance of life, with all its visitations, that distinguishes the free personality who is master of himself.[11] It would seem that the many descriptions currently popular of autonomous individuals are attempts to describe the self-reliant person such as Riesman's "inner directed" individual, Fromm's "productive orientation," Rogers' "fully functioning individual," and Lindner's "rebellious individual." There have been many tests developed to test one's self-attitude from therapeutic interviews to personality tests, but the validity must be questioned in terms of how relevant the procedures are in terms of evaluating mental health, how unnatural are the conditions of testing compared to one's performance in daily living and how valid is the best qualified observer to judge mental health.

Some mention must be made of psychoanalytic thinking on mental health as a means to self-realization and self-accessibility. The outlook of Freud towards preventive mental health was quite pessimistic, a reflection in part of his own personality, but also from his system which held the individual torn between instinctive id-impulses and the rigid inhibitions on these impulses by a restricting external world and a punishing superego. Freud thus regarded a painful adjustment to the cruel reality in which some satisfaction could be obtained and a holding in check of unsatisfiable impulses, "abandoning the pleasure principle," as the only life compatible with mental health. Any other mode of adjustment was regarded as conducive to pathology. This approach stemmed from his holding the ego merely a mediator between impulses of the id and external reality by controlling impulses from the internalized restrictions of the superego. However, many present-day orthodox analysts believe the ego to have a more dynamic role in the mental health of the individual which makes it capable of a more active role on its own part instead of just playing the role of a mediator, envisaging a resolution of mental conflicts not just based on stoical resignation.[12] Thus, Hartmann considers any balance of forces with ego-domination as unsatisfactory. He believes it was inaccurate to consider the most rational (ego-dominated) individual as the most healthy; a healthy ego is able to make use of a system of rational control, but it must also incorporate the irrational as an element in its design, maintaining a mobility or plasticity that allows the balance of forces to shift as needed.[13] Kubie postulates mental health when the conscious-preconscious systems dominate behavior as contrasted with a predominant unconscious origin from unconscious conflicts in which there is a lack of flexibility that freezes behavior into patterns of unalterability, and which predetermines its automatic repetition irrespective of the utility of the acts or thoughts. "The implicit ideal of normality that emerges from this hypothesis is an individual in whom the creative alliance between the conscious and preconscious systems is not constantly subjected to blocking and distortion by the counterplay of preponderantly unconscious forces, whether in the prosaic affairs of daily life, in human relations or in creative activity."[14] Many of these general concepts have been mentioned by others on a lower level of explanation without reference to the theoretical framework of psychoanalysis by referring to a person's ego strength, frustration tolerance, anxiety tolerance, delaying gratification, resistance to stress, as being criteria for mental health.

Mastery of one's environment must be mentioned as it is an often quoted standard of mental health, although its closeness to self-actualization and dependence on self-reliance is obvious. Under this heading are ranged adequacy in love from the ability to experience sexual pleasure[15] to efforts and processes at problem solving. Many of the neo-Freudian contributions by Horney, Fromm, Sullivan *et al* are concerned with impaired interpersonal relations interfering with the ability for environmental mastery. They also lay stress on the

socio-economic and cultural forces conducive to health or illness. Recent work along this line has stressed man's alienation from himself and his fellow men, resulting in an existential anxiety with the facade or semblance of productive activity being a meaningless "keep busy" to avoid facing the reality of oneself.[16]

It has been thought necessary to give an introduction dealing with various aspects of what mental health is considered to be, but it would seem that mental health means many things to different people. There are as yet no specific qualities that one must have to be mentally healthy. Perhaps at the present time the most workable approach would be to accept different types of mental health, not all compatible with each other simultaneously except in an idealized setting, but various aspects of which can be prominent at different times. This would accord with the proposal of Smith for optimal mental health as contrasted with attempts at maximization of every possible function.[17] Then for each situation limited by the individual and his cultural milieu there would be not just one set of criterion values, but a family of such sets to be evaluated in terms of reaching varying degrees of potential with each other.

II

Concepts of detection and prevention are necessarily tied to the epidemiology of mental disease. There is a common feeling that little is known about epidemiology from a tendency to remove from the concept of mental illness those diseases on which epidemiologic knowledge can lead directly to programs for prevention; thus organic diseases such as paresis, traumatic psychoses, post-encephalitic or meningitic psychoses, mental disorders produced by poisons and drugs such as steroids, bromides, isoniazid, belladonna and thiocyanates are often excluded when the problems of detection and prevention are discussed although there is an understanding of the effects of these processes, and programs to avert mental sequelae have been in action for years. Yet, it is true that in regards to these conditions it has been the general progress of medicine that has provided epidemiologic advancement and not preventive psychiatry *per se*. It is also true that the most numerous mental diseases still resist a basic understanding from an epidemiologic point. Considering the most elusive and prevalent psychosis, schizophrenia, there are many factors that hinder preventive programs: (1) Basically, the diagnosis of this disease rests on a clinical evaluation of the patient, the same as some hundred years ago, and even though we have more knowledge about the disease, this is never as reliable as a more objective test to support clinical impressions. At least to the present time no clinical or biochemical test has proven diagnostic. (2) The early manifestations and symptoms of schizophrenia are not fully known and are very difficult to recognize, resulting in progressive cases that are first seen by psychiatrists. Mild cases and the pseudoneurotic form are particularly difficult to detect early. (3) Detection of the disease is also difficult because we do not yet have criteria to say when a person is "officially" schizophrenic.[18] Some can become so in months, weeks and sometimes in a few hours. Thus, the problem arises as to when the person is schizophrenic. Has he just become schizophrenic at the point of his breakdown, or some months previously, or is this just the manifestation of a hereditary tendency and the person has been schizophrenic since the instance his mother's ovum was fertilized by his father's sperm? (4) Even trained psychiatrists vary in their diagnoses of this disease by 30 to 60 per cent, and the diagnosis is thus still unfortunately far too subjective. Some would say the psychological tests should be the laboratory data in psychiatry, but it must be realized that these tests are not on the level of accuracy of the usual medical laboratory work. As they depend on clinical data, conclusions drawn from them are always somewhat circular and subject to the same limitations and subjectivity as clinical impressions. There is also the difficulty with personality tests such as the Rorschach, TAT and MMPI, that patients may co-operate poorly, cover up queer ideas, and yield little workable material to help in differentiating schizophrenics from non-schizophrenics. A point has also been made that personality tests are usually validated against psychiatric diagnoses and therefore can only be used validly to predict which label the psychiatrist who took part in the validity study would have assigned to a patient. If a psychological test "confirms" one's diagnosis, it does not mean one can make a prognosis or decide on treatment with any more confidence as the test has not been validated for that purpose and no correlation shown with prognosis or treatment.[19] (5) We do not know what the etiology of the disease is, whether it is a purely psychogenic disease or due to a metabolic imbalance in the body, or both, or if

hereditary factors are involved or not although each of these viewpoints has ardent, even though not always scientifically inclined, advocates. The question of single or multiple etiology is simply not known at the present time. In fact, even the basic symptoms of the disease are not known. The formulations of Bleuler, made in the nineteenth century, are very probably outdated although they continue to be taught in medical schools with very little having been added to them. (6) We have inadequate criteria for evaluating improvement. It is estimated that about one-third of the patients released from mental institutions who "were" schizophrenic have a relapse, and we do not know if they have just adapted better to their environment while remaining as sick as before, or if the environment adapted itself to a schizophrenic.[20] It seems evident the atmosphere in our hospitals is one to encourage the helplessness and regression of the patient, and actual improvement relevant to how a patient will do in a less artificial setting is difficult.

With all these deficiencies in our knowledge of this disease, one might conclude that the situation was hopeless. Yet, considering all aspects, it might not be. It is known that public health has eradicated many epidemic diseases with insufficient knowledge of exact causes, and many facts are known about mental illness on which to work. Perhaps key links in the natural history of mental illness can be identified, or modifiable environmental features can be observed. There are many areas where this has happened, such as with nutritional deficiencies. The exact mechanism of how nicotinic acid prevents pellagra is still unknown, yet the number of pellagra psychoses has been cut immensely. Delirium tremens is another area where the etiological factors related to alcoholism are still obscure, and some have suggested putting our resources into maintaining the nutrition of alcoholics that might prevent delirium tremens, at least until more is known about causation.[21] Similar programs have been successful in relation to toxic psychoses and infectious precesses. With a disease such as manic-depressive states, there appears to be methods of reducing the length of the illness or at least arresting its progress through electroshock combined with psychotherapy. One study feels there is evidence that monthly shock treatments given to schizophrenics delay remissions, but many patients may resist receiving shock monthly when they feel well, and such prophylaxis may not always work.[22] There is always the possibility that early treatment with tranquilizers may limit the development of certain mental illnesses and much recent work has been in this direction. If one judges by the wide generalities made for each new drug as it appears, one would believe this was eminent, but as with all other new approaches, the apparent results may be due to the "Hawthorne effect" of receiving special attention and increased social stimulation.[23] Despite these *ad hoc* procedures, it is evident that a more fundamental approach must be undertaken, particularly if such conditions are to be detected and prevented before they occur. Gruenberg feels that one of the best ways to systematically prevent mental disorder is by working with those who have been in a mental hospital with a psychosis since this group has a very high rate of psychoses that produce total disability, and according to his data,[24] a small amount of clinical and social energy could reduce the rate of relapse by one-third in these people. There must be a thorough follow-up of discharged patients to prevent relapse and deterioration, and this appears to be a present weakness which merely dispensing tranquilizers at stated intervals does not eliminate.

A few words must be said about the difficulties inherent in mental hygiene work, and why there has been such a lag in progress. Some feel that this is an area not subject to any quantifiable observations, but the problems arising are as factual as those in a more restricted field with less variables. Lemkau points out the similarities and differences between the immunologic changes and temper tantrums that go with a case of pertussis where "the immunologic reaction, occurring at a level of integration comprehensible in terms of chemical reactions, is determined with laboratory tools and away from the patient, whose only contribution is a blood sample. The temper tantrum, however, may not be observable by the person required to evaluate it, since in our culture such reactions tend to be concealed as private family matters. . . . The evaluation of the severity or even the presence or absence of tantrums will have to be on the basis of the prejudiced account of a biased witness. But the difficulty of the evaluation does not change the essential character of the fact or relieve the scientist from taking it into consideration."[25] Other limitations to progress in the field are due to the lack of any suitable experimental animals. Attempts have been made to observe

artificially produced neuroses in animals, but this is a great distance removed from observing changes in blood sugar in animals following insulin injection for example. The results of experiments on humans is thus subject to ethical limitations, and also suffers from the results having to be indicated in language which brings up semantic problems. Many experiments in mental hygiene need generations for observation before conclusions can be drawn, just as in other areas of experimental medicine where laboratory animals suffice, and the limitation here is obvious. Only within the last few years have studies been organized so observations of individuals can be made over a long-time period where significant factors can be singled out for evaluation; and even here the methodology in personality evaluation is changing rapidly so that standardization of methods in long-term experiments is difficult. Experiments are most valuable if the variables can be controlled and the experiment repeated. But this is never possible with man, at least in observations over any length of time. There is also the problem of comparing clinical results from one era with another, and from different clinics. Questions of statistical comparison make interpretation hazardous such as in considering when a case becomes a case; some studies consider a patient a case when he appears at a clinic, while others consider a patient a case after the completion of intake processing, which itself may vary from assigning a case by rotation, following minimal identifying information, versus a complete history, physical and psychiatric examinations, and psychological testing.[26] Data collected by various approaches may vary the figures obtained. Thus, the "closed case" method, taking cases closed during a given period, may give results different from the "open" method where cases opened in a stated time interval are followed, and both may differ from the "survey" method where the cases in treatment on a specific day are followed up and considered a typical cross section.

Some of the blame for inadequate progress must rest with the paucity of work that has been going on in basic research on mental health and disease due to the small number of psychiatrists engaged in this work. It is well known that academic psychiatrists are below par financially and prestige-wise compared to those in private practice, and in other professions. The public and many physicians seem to regard the man who enters an academic career as one who could not make good in private practice. The feeling that we had enough basic data on behavior and neurophysiology, with an increasing awareness by the public of mental illness, led to pressures and emphasis for immediate results with a neglect of basic research for applied science. However, the incidence or recurrence of mental disease has so far not decreased even though discharge rates from hospitals have improved. Out of a total federal budget of $77 billion in 1960, only $5.5 billion (7 per cent) is being spent on research and development, and out of this only $500 million (0.65 per cent) is for basic research.[27] Ruesch stresses the atmosphere in the United States that militates against basic research which has those showing promise in an academic setting being shifted into an administrative position, such as deans or department heads, with greater prestige, and serving as the model of achievement for students and younger men as an organizational administrator and not a research scientist. He notes that most creative ideas and themes in psychiatry have originated in Europe, and adds that "no medical, psychiatric or scientific discovery has ever been made by a bureaucrat, nor has he ever advanced new theories or points of view."[28]

There is the problem of whether it is possible to prevent or change attitudes that are inimicable to the mental health of individuals, and much controversy has arisen over whether personality changes are truly possible which penetrates to the heart of the question, if such a thing as preventive psychiatry can ever be a successful actuality. One view is that the developmental stages are quite fixed once they have occurred, such as in infancy, oedipal and latency periods and true modification can only come from depth procedures such as psychoanalysis. To adopt this view is to become extremely pessimistic, for the applicability to a large segment of the population of such a procedure is impossible, not only from the financial limitation, but from the inadequate number of psychoanalysts and the limited number of people that qualify for a successful analysis. The question then arises as to the efficacy of environmental educational influences. Psychoanalysts would probably agree that even if everything went relatively well up to latency, social factors may still have a severely disturbing impact, and the concept of regression would exemplify such a personality change as the result of a particular environmental stress in later life.[29] The crucial importance of

community influence is seen by its impact on parents as they will transmit this influence to their children from birth on, and through behavior changes demanded by environmental pressures which may establish permanent patterns.

Basic to any preventive program for mental illness is getting at the attitudes of people. Attitudes may be regarded as the emotional and intellectual make-up of a person that determines his beliefs and reactions to opinions and facts bearing on these beliefs. The important thing about attitudes is that their origin and development is largely unconscious and from periods of life no longer within the range of memory. The person holds these attitudes not as subject to being proved, but as right because they are right; he rejects any suggestion that they are capable of interpretation on the basis of past personal experience and argues about them on some falsely logical ground. A deduction from this explanation is that as all attitudes have an emotional component, they can be changed most effectively only when emotional approaches are used in the procedure of change. For correction of basic factors important in the development of mental illness, the emotional factors underlying the attitudes will have to be dealt with, and some sort of corrective emotional experience along with logical explanation is needed if fundamental changes in attitudes are to be expected. The application of mental hygiene principles in an attempt to modify these attitudes in different fields will be discussed below.

Even though psychoanalysis is not available for the majority of the population, many of its conclusions have a direct application to the problem of mental health, for it is by utilizing many of its techniques and derivations therefrom that an evocative approach, that has been mentioned above as crucial to any successful mental hygiene program, may be used to reach people. It is admitted that one great advantage of the original Freudian view was that it discouraged the unrealistic optimism that subsequently developed about solving the problems of mental illness. Such a view was not conducive to many positive programs along preventive lines, but it did provide the stimulus for finding out more of the complexity of the human mind, and it developed principles that have direct bearing in the mental health movement, although the acceptance of such scientific foundations was dependent on the historical pioneer work of people like Philippe Pinel, Dorothea Lynd Dix and Clifford Beers. Among the principles of preventive psychiatry which have been developed are the following: (1) The support of parents in the control of a child's impulses until he acquires the power to control them himself, and that in the absence of such support, he becomes the prey of pathogenic anxiety. (2) The importance of home conditions calculated to promote the general emotional maturity of a person. (3) Anticipate the trauma associated with separation from the mother, birth of a sibling, or an operation so the child will not meet it unprepared. (4) The emotional need of the child for attention from both parents. (5) The importance of safe-guarding the child against situations calculated to promote jealousy. (6) Educating parents to not force toilet until the child is psychologically capable of responding. (7) In matters of discipline, understanding the child's needs rather than using rigid discipline. (8) The importance of safe-guarding the child against any risk of being a witness of sexual intimacies between his parents. This includes avoiding premature excitation of sexual feelings and avoiding exaggerated condemnation if it occurs. In line with this principle is a recent law in Israel that forbids the appearance in court of a child under fourteen years of age who has been sexually assaulted as it was realized that there may be more suffering from appearing in court and being cross-examined than from the actual assault episode.[30] This clinical knowledge must be applied for constructive social health through a program of education for and through our social institutions that reach children such as the family, school, church, et cetera. The more that is learned about the psychological needs of children and the demands our society puts on them, the more it becomes obvious that education should focus upon, and develop the potential resources of, individuals in ways that fit them for participating in work, family life and citizenship. This educational task is gigantic and needs much planning, personnel, research and financing, but to ignore it may have consequences analagous to the failure of our government to undertake the needed support for the development of other scientific and educational programs.

(To be concluded in the May issue)

The Minnesota Academy of Medicine

An Historical Account

CARL B. DRAKE, M.D.
Saint Paul, Minnesota

THE FIRST scientific meeting of the Minnesota Academy of Medicine was held on October 12, 1887. The period from then until now has seen greater progress in medical science than did all the preceding ages. To cover the Academy's more than seventy-year history within reasonable time limits permits only a very summary account. I have chosen to focus this brief history on the progress in medical thought during the society's lifetime as indicated primarily by certain selected presentations made at its meetings. For this purpose, I have drawn on the ten volumes of Academy minutes on file in the Manuscript Department, Minnesota Historical Society, and on the excellent summary of the society's first thirty years given in the presidential address of Dr. Arthur S. Hamilton[1] in 1923.

The Academy's Beginnings

On October 1, 1887, Dr. John F. Fulton of St. Paul came to Minneapolis to enlist the help of Dr. A. W. Abbott in founding a society of those physicians interested in original work. The two invited a group of physicians from the Twin Cities to meet on October 7, 1887, at the West Hotel in Minneapolis.† At that meeting temporary officers were elected, and the responsibilities of selecting a membership list of Twin Cities physicians and of drawing up a constitution and by-laws for the new Minnesota Academy of Medicine were assigned.

At the first scientific meeting on October 12, 1887, the twenty-three members present elected the following slate of permanent officers: Dr. John F. Fulton, President; Dr. A. W. Abbott, Vice President; Drs. Richard Olding Beard and Edward C. Spencer, Secretaries; and Dr. LeGrand N. Denslow, Treasurer.

At the Academy's second meeting, held at the Ryan Hotel in St. Paul on November 5, 1887, Dr. Fulton as President advised all members to have "something to say" and to say it briefly. He continued his inaugural address by stating, "A so-called specialist whose education is not well founded in the art and science of general medicine is not worthy of recognition by the profession."

From 1888 to 1900

A thesis entitled "Sepsis and Antisepsis in Mid-Wifery" was read by Dr. A. B. Cates in January, 1888. Dr. Cates pointed out that only seventeen years had passed since the first attempt at antiseptic midwifery, only six years since corrosive sublimate had been used, and only four years since thorough and complete antisepsis had been observed. Yet as a result of this advance in technique, the death rate from puerperal infection had already been dramatically reduced—from 11 per cent to less than 0.5 per cent.

On May 4, 1889, Dr. C. H. Hunter read a paper entitled "A Note upon intubation," reflecting the interest in that subject since four years earlier when Dr. Joseph P. O'Dwyer of Cleveland described the use of his new intubation tube designed with a bulge to prevent easy expulsion and a lip to preclude loss of the tube in the trachea.[2]

In December, 1890, Dr. James E. Moore presented a specimen of a plaster dressing to illustrate the tightness and firmness of this apparently new type of dressing. White of egg applied to a bandage and allowed to dry was commonly used in the early days to furnish a supporting dressing.

Dr. William J. Mayo read a paper in 1890 entitled "A Discussion of Some Features of Peri-uterine and Perityphlitic Abscesses."[3] He had operated upon ten patients with perityphlitic abscess following ulcerative appendicitis, with nine re-

Read before the Minnesota Academy of Medicine on April 9, 1958.

†The group included: Drs. Allport, Abbott, Beard, Bracken, Braunsteen, Dunn, Hall, Hunter, and Wells of Minneapolis; and Drs. Denslow, Fulton, MacLaren, Millard, Owens, Riggs, and Spencer of Saint Paul.

coveries and one death; and he had treated six patients with periuterine abscesses—three by a mid-line incision and three by vaginal drainage—with six recoveries. For years the average physician, satisfying himself in these two conditions with a diagnosis of inflammation of the bowels, had prescribed laxatives and enemata. Dr. Mayo stated that the best time to operate was difficult to determine but that adhesions might limit the process and make the period from the fourth to eighth day period the optimal time. Both Dr. Mayo and Dr. Reginald H. Fitz, in his monumental article on appendicitis[4] written four years earlier, were advocating the operative treatment of the complications of appendicitis; and it was not until later that physicians realized the importance of operation before complications had arisen.

The celebrated Dr. William Osler of Johns Hopkins was a guest at the October 5, 1892 meeting. After a dinner given in his honor, the meeting was adjourned to the chamber of the House of Representatives at the old State Capitol where some 200 members of the medical profession assembled to hear Dr. Osler speak on "License to Practice." In 1893 he was elected an honorary member of the society. Another illustrious physician, Dr. Charles H. Mayo, was elected to associate membership on January 4, 1893, and he read his thesis on "Skin Grafting" on March 1, 1893.

In March, 1896, Dr. C. G. Weston read his inaugural thesis on "Antitoxin Treatment of Diphtheria." Three years before, in 1893, the German Emil A. von Behring, had first prepared diphtheria antitoxin and in 1894 had made it generally available.

In October, 1896, Dr. Perry H. Millard extended an invitation to the members to attend at the University of Minnesota a semi-centennial celebration of the discovery of anesthesia.

Another paper by Dr. William J. Mayo was given in February, 1898, entitled "Observations upon the Diagnosis and Surgical Treatment of Certain Diseases of the Stomach." It reveals his early interest in stomach surgery. These observations were never published, and from the discussions which were published one cannot be certain that his advocacy of gastroenterostomy for duodenal ulcer began as early as 1898. A few years later, however, Dr. Sippy of Chicago recommended medical treatment of peptic ulcer with alkalis and frequent feedings. Feeling between the two camps—surgical vs. medical treatment—was occasionally intense. A generation or so later, in his address before the Academy on May 8, 1935, Dr. Donald C. Balfour of Rochester gave an excellent presentation[5] of the indications for surgical treatment of ulcer; with the improvement of medical management by this later date, a smaller percentage of cases had come to require surgery.

From 1900 to 1910

In June, 1900, Dr. Rothrock reported on a case of thrombosis of the coronary artery with sudden death (not published). This was twelve years before Dr. James B. Herrick of Chicago was to publish his famous article, "Clinical Treatment of Sudden Obstruction of the Coronary Arteries,"[6] which pointed out that the coronaries are not end arteries, and that recovery from thrombosis of these arteries frequently occurs. I was not able to find any record of a paper on coronary thrombosis having been presented during the decade after Herrick's article. A fine paper,[7] however, on the differences between angina pectoris and coronary occlusion was given by Dr. S. Marx White at the April 11, 1934 meeting.

The Academy took part in the agitation for a state-supported tuberculosis sanatorium. Certain medical groups vigorously opposed such an undertaking on the ground that the state would be entering into the practice of medicine in an unwarranted field. Dr. Henry Longstreet Taylor, a member of the Academy, was among the first physicians, if not the first physician, in this state to specialize in the treatment of tuberculosis. The belief that the ozone of Minnesota's pine woods had a healing effect on pulmonary tuberculosis had induced many sufferers to move to Minnesota. Dr. Taylor became convinced that the treatment of tuberculosis—consisting in those days largely of prolonged rest, full diet, and often absurd amounts of fresh air—was not attainable for the average patient with family responsibilities. He therefore led a crusade, writing articles for the public and speaking in church pulpits and elsewhere to urge establishment of a state tuberculosis sanatorium. On December 6, 1900, he presented a resolution, which the Academy adopted, asking that the State of Minnesota establish an institution for the treatment of "early cases of consumption."

On May 1, 1901, Dr. J. G. Cross who was then with the Mayo Clinic* presented his thesis[8] on "The Present Status of the X-ray in Medicine and Surgery." The x-ray had been discovered by Roentgen only five years earlier, but surprising progress had already been made in its application to medical diagnosis. Dr. Cross pointed out that the fluoroscope was being used for observing the thorax and its contents; he stated that while the radiograph was of value in locating opaque foreign bodies and fractures of the extremities and even diagnosing kidney stones, the rays were not penetrating enough to produce satisfactory plates of the hip joint, pelvis, or spine. Intrathoracic aneurysms and tuberculous joints and lung cavities could be shown clearly, as could dilatation and diverticula of the esophagus.

On October 7, 1903, Dr. Richard Olding Beard resigned after fifteen years as secretary, and Dr. Arthur A. Dunning was elected to succeed him.

At the January, 1907 meeting, when pediatricians were apparently just becoming cognizant of the condition, Dr. Walter Ramsey described two fatal cases of pyloric stenosis in infants. Nine years later, at the meeting of January 5, 1916, Dr. Arthur A. Law reported on a fatal case of pyloric obstruction in an infant upon whom he had performed a gastroenterostomy. In 1912, Ramstedt,[9] the German surgeon, had advocated simply incising the obstructing muscular ring at the pylorus, a much simpler operation which greatly reduced the surgical mortality in the dehydrated and undernourished infant.

From 1910 to 1920

At the meeting of November, 1910, Dr. Justis Ohage, a member of the Academy, recounted the history of the first complete removal of a gallbladder in the United States; the operation had been performed by him in 1886, and it was reported before the Ramsey County Medical Society (*Medical News,* Feb. 19 and Feb. 26, 1887). Dr. Ohage reported that he had sacrificed the lives of about eighty dogs before attempting the operation on a human patient.

The treatment of syphilis received considerable attention from Academy members. Thus, at the June, 1912, meeting Dr. Woodard spoke on the use of salvarsan in the treatment of this disease, and Dr. John Armstrong stated his belief that that drug constituted the best treatment then available. Two years later, in February, 1914, Dr. Charles D. Freeman presented his thesis[10] entitled, "Recent Advances and investigations in the Treatment of Syphilis with Special Reference to Syphilis of the Nervous System." He stated that syphilis would always be with us unless a way was found to establish immunity by vaccination. Dr. Freeman stated that the treponema could be demonstrated in 80 per cent of primary lesions and that the recent finding of the treponema in the brain and cord in cases of paresis and tabes by Noguchi had proved that these two diseases were of luetic origin. It had not been proved, however, that the treponema in the nervous tissues could be reached by mercury or salvarsan in the circulation or in the spinal fluid. Dr. Freeman was not enthusiastic about the Swift-Ellis treatment then in vogue but since abandoned.

On November 4, 1914, Dr. George Douglass Head introduced a bombshell when he read a paper entitled, "Tuberculosis (concealed): A Heretofore Unrecognized Clinical Type of Tuberculous Infection." He deduced that many neurasthenic symptoms when accompanied by a positive tuberculin reaction were caused by a concealed active tuberculous infection. Other members in discussing his paper felt that the x-ray was more reliable than the tuberculin test in unearthing otherwise concealed tuberculous infection. Dr. Head was so convinced of the importance of his discovery that in 1924, he published a book entitled *Concealed Tuberculosis or the Tired Sickness.* It was subsequently established, of course, that a positive tuberculin reaction indicates previous infection, active or inactive.

While World War I was absorbing the attention of many physicians, several events are noted in the Academy's history. Dr. Arthur W. Dunning, after ten years as secretary and treasurer of the society, was elected president in December, 1915, and died while in office. On March 14, 1917, a silver gavel, made by an eastern silversmith, with the names of the presidents of the Academy engraved upon it was presented to the society by Dr. Frank C. Todd. At the October, 1917, meeting Dr. Robert E. Farr reported some of the operations he had performed under local anesthesia—herniotomies, removal of a tumor from an arm, craniotomy, reduction of a dislocation, resection of an unruptured tubal pregnancy.

*He moved to Minneapolis in 1904 practicing in the field of internal medicine.

Dr. Cornelius Williams died on December 29, 1918. A pioneer in the field of mastoidectomy, at that time the third most common operative procedure, he preferred a dental burr as permitting greater thoroughness than the conventional chisel and mallet, a judgment that time was to vindicate.

From 1920 to 1930

When Dr. Harry P. Ritchie became secretary-treasurer upon the resignation of Dr. Leavett on November 10, 1920, he recommended appointing an official reporter to record the society's proceedings. Miss Goldie Crever took over the duties of this post on April 11, 1921, and has held the position ever since. Miss Crever not only recorded actual proceedings, but also compiled a summary of the activities of the society during its first fifty years, a list of the charter members, the names of the presidents and dates and titles of their addresses, a complete record of meeting dates and places for the first fifty years, and an index of the members' contributions to each meeting. This valuable material, bound in a single volume, was presented to the Academy by Miss Crever at the meeting of January 11, 1939, to remain in the custody of each successive secretary. Other duties of this post have included filing the submitted theses, addresses, and case reports in the minute books which are kept in the archives of the Minnesota Historical Society.

A report on an electrocardiographic and clinical investigation of the therapeutic value of camphor[13] was presented at the January, 1922, meeting by Dr. E. T. F. Richards in conjunction with Dr. R. Edwin Morris. They reported that camphor injected intravenously in dogs led to convulsions followed by a toxic period with a succession of heart block, stoppage of respiration, ventricular and then auricular failure, and finally, periods of ventricular fibrillation. They concluded that camphor does not stimulate the heart, as had been widely held. Dr. F. H. Schultz cited his own experience to support this thesis. He told of taking 2 cc. of camphor in oil orally before breakfast one morning. He reported that as a result his skin had become cold and clammy, he had felt nauseated, his pupils had become dilated, and tremor and a staggering gait developed. For years camphor in oil, injected intramuscularly had been the remedy prescribed when the patient seemed to be dying. It would seem from the experiments cited above, that by injecting camphor in oil the physician in many cases was inadvertently contributing the *coup de grace.*

In discussing an address given before the society at its December, 1922 meeting, Dr. L. C. Bacon told how a well-known physiologist *(sic)* had come to the University of Michigan in the eighties and had been asked by Dr. Vaughn to make an estimate of the capacity of the members of the senior class in the medical school. Among those whom the physiologist considered unfit for the medical profession were Dr. W. J. Mayo and Dr. Walter Courtney (later of Brainerd). Commenting on this obvious failure of judgment, Dr. Bacon suggested that there are many factors in the mental processes of young people which cannot be "measured by rule of thumb." When the society met at the Kahler Hotel in Rochester on November 12, 1925, Dr. John F. Fulton, the first president of the society, made some introductory remarks, and the scientific program was given by members of the Mayo Clinic.

At the September, 1926 meeting, Dr. Henry Ulrich gave his presidential address on "Some Aspects of Hypertension."[15] His definition of essential hypertension and its course is acceptable today: He describes essential hypertension as a definite clinical syndrome which may lead to cardiac failure, vascular accident, encephalomalacia, or renal insufficiency. Arteriosclerosis, he maintains, is not the cause, but rather the effect of the hypertension; the resulting vascular kidney is distinct from the contracted kidney of Bright's disease. He states his belief that a vasomotor center, probably in the medulla, controls the smooth fibers of the precapillary arterioles by way of the vegetative nervous system. Any factor that produces a contraction of the arterioles will narrow the peripheral vascular field and cause an automatic increase in the blood pressure to maintain proper circulation. This may result in arteriosclerosis or in a fixed tonus in the muscles of the arterioles. Cholesterin, he says, is the only metabolite which has been found so far to be increased with any degree of consistency in hypertension, and Westphal feels justified in assuming that cholesterin is a tonogenic substance. Dr. Ulrich's investigation in 1926 of the blood cholesterol in a series of seventy-four hypertensive patients, and his demonstration that by and large hypercholesteremia and hypertension go hand in hand, were

fine examples of pioneering research on blood cholesterol. His presentation in 1926 of the nature of essential hypertension is the conception that has persisted to the present.

At the October, 1926 meeting, Dr. Henry Ulrich reported on an apparently hypoglycemic patient whose wife had to sit up nights feeding him candy and orange juice. Strangely enough, his blood sugar tolerance curve was typical of diabetes. One member predicted that the patient would eventually prove to be diabetic. The patient later went to Rochester and was given continuous intravenous glucose until subjected to surgical exploration. Carcinoma of the islands of Langerhans with metastasis to the liver was found, and insulin was obtained from the liver metastasis. The case was later reported by Dr. Russell Wilder. (On March 13, 1946, Dr. Martin Nordland reported a case[14] of islet cell tumor of the pancreas with recovery from the symptoms of hyperinsulinism after removal of the tumor—an adenoma. Some 150 cases of adenoma of the islands of Langerhans had been reported before Dr. Nordland reported his.)

At the May, 1929 meeting, Dr. Ulrich presented a report of a case of coarctation of the aorta, the first he had encountered. Dr. James S. Gilfillan stated he had been watching for such a case for twenty-five years but so far had not observed one. No other member volunteered any personal experience with this congenital anomaly.

In August, 1929, Dr. Everett K. Geer gave his thesis on "Avulsion of the Phrenic Nerve for Pulmonary Tuberculosis." The discussion that followed brought out that in treating of tuberculosis, rest was still the main objective toward which end the surgical methods of pneumothorax, avulsion of the phrenic nerve, and the mutilative operation of thoracoplasty were all directed.

The first Academy medal, for the most noteworthy contribution to the scientific program of the society during the year, was awarded to Dr. Arnold Schwyzer on December 11, 1929. The medal was awarded not for any one contribution, but for Dr. Schwyzer's reports of his routine work covering a wide field, and for his interesting and constructive discussions of the work of others. Dr. Alexander Colvin made the presentation, and it was he who fifteen years later wrote and read the outstanding tribute to Dr. Schwyzer at the meeting on May 10, 1944, following Dr. Schwyzer's death.

In his presidential address, "Essential Hypertension," given at the January, 1930 meeting, Dr. C. N. McCloud reminded his audience that it was not until 1906 that blood pressure instruments had been perfected for general clinical use, and not until 1918 that the auscultatory method was adopted and the importance of the more stable diastolic reading realized.

From 1930 to 1940

On May 17, 1930, a Founders Dinner was held for the living founders of the society at the Minnesota Club: Richard Olding Beard, J. W. Bell, William Davis, F. A. Dunsmoor, John F. Fulton, W. A. Jones, T. S. Roberts, Frank Allport, Justus Ohage and H. M. Bracken. (Doctors Allport, Bracken, and Dunsmoor were unable to attend.) All the founders present spoke. Dr. Davis pointed out some interesting changes in vital statistics that had occurred since the society was founded. In 1887, cholera infantum had headed the list of causes of death, and along with allied intestinal infections it accounted for 400 deaths in Saint Paul alone in that year. Pneumonia was responsible for half that number of deaths, typhoid fever was third in the list, tuberculosis fourth, and diphtheria fifth. Carcinoma held sixteenth place. Very few babies were born in the hospitals in 1887, whereas four-fifths were born in the hospitals in 1929. In 1887, chloroform and ether were equally used as anesthetics. Bichloride of mercury was taking the place of carbolic acid as an antiseptic; asepsis and sterilization by heat were introduced several years later.

Dr. James Gilfillan read his presidential address on "Compulsory Health Insurance" in January, 1932. He stated that in 1917 the American Association for labor legislation had caused to be introduced in the legislatures of twenty-two states a bill to provide compulsory health insurance to all employes. It stipulated that all administrative expenses were to be paid by the state, and that insurance premiums were to be paid equally by employers and employes. The bill provided the disabled employe with a certain percentage of wages, medical and hospital care, drugs, dental care, expenses of rehabilitation and burial allowance for himself and family in case of need. This legislation if passed would have guaranteed complete health care for all employes and their families through compulsory government insurance with the medical profession in the employ of the

state. Dr. Gilfillan pointed out the continuing efforts that had been made to institute state medicine on a state or national scale since that date.

In May, 1932, Dr. E. B. Foley described his new Foley prostatic excisor which led to improved methods of treating prostatic obstruction.

At the same meeting Dr. O. H. Wangensteen presented his thesis on "Therapeutic Considerations in the Management of Acute Intestinal Obstruction." Dr. Wangensteen's institution of nasal suction in postoperative care and in intestinal obstruction was an original piece of work which brought him international recognition.

The "Status of Obstetrical Practice in Minnesota" was the topic on January 11, 1933, of Dr. J. C. Litzenberg's presidential address. He pointed out that the maternal death rate in Minnesota had become the lowest in the country, having dropped from 7 to 4.3 per 1,000 live births during the period from 1915 to 1929; deaths due to puerperal sepsis had decreased from 2.9 per 1000 live births in 1920 to 1.8 in 1929. (Incidentally, in 1954 only three deaths from puerperal sepsis occurred in 80,580 live births in Minnesota.) Dr. Litzenberg has been given much of the credit for the state's top rank in the field of maternal welfare.

At the March, 1933 meeting, Dr. W. H. Condit spoke on "Trichomonas Vaginalis Vaginitis," a subject that had received scant attention from gynecologists until 1931, when Greenhill[16] made his report on the disease before the Chicago Gynecological Society.

At the March, 1935 meeting, Dr. Harry P. Ritchie spoke on the subject of his special concern and greatest contribution—"The Congenital Clefts of the Face and Jaw." Dr. Ritchie acquired national recognition for his pioneer work in the operative treatment of these congenital defects.

At the same meeting Dr. Robert G. Green presented his thesis on "The Epizoötiology of Tularemia in Minnesota," an outstanding piece of original research. Dr. Green had discovered that tularemia is highly fatal in cottontail rabbits but relatively mild in the snowshoe variety; that grouse are more susceptible than the snowshoe rabbits; that wood-ticks are principally infected from the small rodents and not from the rabbits. The highest incidence of infection of wood-ticks he had found to be 0.25 per cent; the greatest hazard of infection of humans from the tick was found during May and June, and from animal contact during September and October.

On January 13, 1937, Dr. Thomas S. Roberts gave as his presidential address an interesting review of bird life in Minnesota. He was, of course, an authority on bird life and the author of the famous two-volume edition on Minnesota Birds.

The memorial to Dr. John T. Rogers[16] by Dr. Harold E. Hullsiek, read at the April 13, 1938 meeting, is a masterful account of a colorful career.

In conjunction with the first use of the sulfas, Dr. Moses Barron spoke on "Some Use of Sulfamidopyridine Preparations in the Treatment of Infectious Diseases" at the meeting of April 10, 1940, and noted that he had been favorably impressed by some of the results obtained. Dr. Zierold reported that the local use of sulfas had brought good results in compound fractures and had reduced infections from 30 to 1 per cent in patients at the Minneapolis General Hospital. Others reported good results from the use of sulfanilamide in intestinal operations on dogs.

From 1940 to 1950

On December 10, 1941, Dr. Max Hoffman and Dr. F. E. B. Foley presented a case of "Adrenogenital Syndrome Due to an Adrenocortical Tumor." Dr. Hoffman had been much interested in endocrinology and had established a laboratory with the assistance of public funds for the study of glandular secretions. Dr. Hoffman described a patient who had excessive hair on her torso as well as on her face and was losing the hair on her head. A tumor in her right flank was demonstrated by air injection and x-ray. Dr. Foley removed a large adrenal tumor with great difficulty, an operation which he recorded on color film. Following the surgical procedures, certain of the patient's masculine features disappeared and her normal hair distribution returned. (The case report was never published.)

On January 14, 1942, Dr. John Armstrong, in a paper on "Asiatic Cholera in Saint Paul," told how Asiatic cholera gained entry into this country in the mid-nineteenth century from Canada by way of Detroit, Michigan, and up the Mississippi River. In 1849, a Mr. L. B. Larpenter, aged seventy-one arrived in St. Paul by steamboat up the Mississippi River and died of cholera a few days later. A few more cases of cholera occurred in 1849 and 1850, and a small epidemic broke out in 1853 and 1854.

In the nineteen forties, the medical profession was much disturbed by the efforts being put forth in Congress to put medicine in the hands of the federal government. Each year a Wagner-Murray-Dingell bill was introduced in Congress, and at the January 12, 1944 meeting Dr. Harry B. Zimmermann gave his presidential address on the subject "Organized Medicine and the Wagner-Murray Bill." He emphasized the need for the medical profession to direct medical education through its established boards if state medicine should come, inasmuch as the medical profession alone knew the requirements for practitioners and specialists. He expressed the belief that state-controlled medicine was likely to come and that all the medical profession could do was to see that as little harm as possible was done to the practice of medicine.

At the January, 1947 meeting, Dr. Sam E. Sweitzer reported that he had found penicillin suitable in treating chronic as well as acute cases of syphilis, provided that its administration was preceded by bismuth and potassium iodide to prevent a Herxheimer reaction.

At the annual president's meeting held January 14, 1948, the living former presidents were guests of honor, and Dr. Ernest M. Hammes gave the presidential address on "The Drug Addict." Later that year in October, 1948, Dr. Wesley W. Spink spoke on his experience with the use of the new antibiotic Aureomycin® one of many antibiotics developed following the discovery of penicilin.

In November, 1950, Dr. Charles H. Slocumb of Rochester gave an unpublished paper on the use of cortisone and ACTH in rheumatoid arthritis. Since Dr. Edward C. Kendall of Rochester was the first to produce cortisone and since Dr. Philip Hench, also of the Mayo Clinic, was the first to use it clinically, the topic naturally had special interest locally.

I have carried my hasty review of the proceedings of the Academy through the year 1950. I beg the indulgence of the many members of the society — perhaps the majority — whose valuable contributions I have not been able to mention.

By and large, the suggestion made by the first president, Dr. John F. Fulton, that members have something to say when they address the Academy has been followed. The contributions have been largely reports of personal experiences and reviews of the pertinent literature, covering nearly all the specialties. Thus the members have been given an opportunity to broaden their medical knoweldge, an educational endeavor which, according to the first president of the Academy, is important even for a specialist.

The publication of the proceeding of the Academy, first in the *Northwestern Lancet,* then in the *Journal Lancet* and the *St. Paul Medical Journal,* and later in MINNESOTA MEDICINE has made the programs more widely available. Unfortunately, the proceedings of the Academy have not been published for the past four years, and I feel that every effort should be made to resume publication. It has been unfortunate to my mind, that some of the members through unjustifiable modesty or inexcusable lethargy have failed to turn in their presentations for recordings and publication. The Academy can be proud of its past, and it deserves the best efforts of its members to keep it in the vanguard of medical progress.

Acute Necrosis of the Right Rectus Abdominis Muscle Simulating Acute Appendicitis

LOUIS C. LICK, M.D.
L. J. SWANSON, M.D.
Saint Paul, Minnesota

ACUTE conditions involving the abdominal wall must be considered in the differential diagnosis of the acute abdomen. The following case report is presented.

Case Report

Mr. E. V., a white man aged thirty-three, was admitted to the Riverview Memorial Hospital on August 25, 1957. He complained of severe pain in the right lower abdomen which had begun six hours prior to admission to the hospital. The pain was constant and made worse by coughing.

He stated that he had a "soreness" in the same area for four to five days, also made worse by coughing or sneezing. There was no nausea or vomiting, and he had a normal bowel movement the morning of admission. There were no genito-urinary complaints. There was no history of any abdominal injury.

Past history revealed mild ulcer-like symptoms ten years previously which promptly disappeared after medical therapy with no recurrence. He had never had any abdominal surgery. He was employed as a truck driver.

The patient was a very well developed and heavily muscled man in acute distress. His oral temperature was 99.8° F. Blood pressure and pulse rate were normal. Positive physical findings were limited to the abdomen.

There was marked tenderness in an area three inches to the right and just below the level of the umbilicus. There was no discoloration of the skin of the abdominal wall. The abdomen was not distended, and no bowel sounds were heard on auscultation. Marked muscle guarding was present in the area of tenderness. Rebound tenderness was not present. There were no palpable masses in the abdomen. Digital rectal examination was negative, and there was brown stool in the rectum.

It was extremely difficult for the patient to sit up, since this movement accentuated the abdominal pain. No mass was felt during this maneuver.

Laboratory studies revealed a normal urinalysis and hemoglobin. The leukocyte count was 12,200, with 47 per cent neutrophiles, 49 per cent lymphocytes, and 4 per cent eosinophiles. The Kline serology test was negative. Roentgenograms of the chest and abdomen (including an upright position) were negative.

In evaluating this condition, it appeared that the marked abdominal tenderness, which was well localized, was out of proportion to the other findings. An acute surgical abdomen seemed certain, however, and the patient was taken to surgery for abdominal exploration.

Under general anesthesia, a 10 cm. right paramedian incision was made directly over the area of maximum tenderness. When the anterior rectus sheath was incised, approximately 2 ounces of thin, xanthochromic fluid gushed out of the rectus sheath, and a complete gap in the right rectus muscle was found. The defect measured about 6 cm. in length. There was no hematoma, and while the muscle edges above and below the defect were ragged, there was no bleeding from the muscle edges.

The muscle edges were debrided, and the peritoneum was not opened. A small split Penrose drain was placed at the bottom of the rectus muscle defect and brought out the lower end of the incision. The incision was closed in layers with interrupted silk sutures.

Convalescence was uneventful. The drain was removed on the fourth postoperative day and the patient discharged from the hospital the same day. He was last seen three months after surgery, at which time the operative site was as strong as the opposite side. He had resumed his heavy work two months after surgery with no ill effects.

Discussion

This case was diagnosed as necrosis of the rectus muscle since proof of rupture of the muscle or

hematoma in the muscle could not be proved. It is possible, of course, that rupture of the muscle did occur. However, the patient could not recall any sudden onset of pain after exertion which one would expect if this broad muscle had suddenly ruptured.

TABLE I. PHYSICAL FINDINGS[2]

Symptoms	Number Cases	Per Cent Total Cases
Pain	51	100
Localized tenderness	51	100
Elevated white blood counts	20	39
Gastro-intestinal symptoms	16	31
Elevated temperature	21	41
Upper respiratory infection	10	20
Grossly palpable hematoma	10	20

A brief review of the literature revealed a number of reports of this condition. The majority of the papers concerned single case reports. Two cases were reported in this journal by Eiler in 1956.[1]

Most of the cases were reported during World War II. Fruin and McLaughlin[2] reported fifty-one cases of rectus muscle strain occurring in trainees at a naval training station. Forty of the cases involved the right lower rectus muscle. The histories and clinical findings were very similar in that all patients had undergone violent exercise just prior to the onset of their symptoms. The authors presented Table I listing the essential physical findings.

They suggested procaine infiltration of that portion of the abdominal wall as a diagnostic test whenever rectus muscle strain, rupture, or hematoma is suspected.

Bowers and Richard[3] reported a similar experience from an Army training camp. They advocated conservative treatment with absolute bed rest, local heat, and oral medication for relief of pain.

Teske[4] stressed the occurrence of this condition in aged, debilitated patients with advanced arteriosclerosis. The inferior epigastric artery may be weakened and rupture after exertion such as lifting, coughing, or sneezing. He advocated exploration of the rectus sheath, evacuation of the hematoma, ligation of any bleeding vessels, debridement of non-viable muscle ends, and layer closure of the incision, with or without drainage.

Martin and Thompson[5] reviewed the literature and suggested a Zenker type degeneration of the muscle. These authors noted a number of cases of rectus muscle rupture during the pandemic of influenza in 1917-1918. Zenker's degeneration of striated muscle is said to accompany influenza.

Brödel[6] made an exhaustive detailed study of the anatomy of the rectus muscle. He pointed out several factors which might predispose hemorrhage in the lower portion of this muscle. This part of the muscle contracts a greater distance than the upper portion, due to lack of tendinous inscriptions. The inferior epigastric vessels lie deep to the muscle along the lower portion and hence are exposed to trauma during contraction of this portion of the muscle. Also, the posterior rectus sheath is lacking below the semicircular line of Douglas, and hemorrhage below this line may extend a greater distance as well as across the midline to the opposite side.

The extreme stretching and thinning of the rectus muscle during the latter stage of pregnancy would account for the cases of rectus rupture or hematoma which may occur during the last trimester of pregnancy.

Summary

A case of acute necrosis of the right lower rectus muscle has been presented. The diagnosis was made at the time of surgery, and debridement of the muscle edges with drainage of the rectus sheath was done. Recovery was prompt, and no postoperative hernia developed. The treatment of this condition may be non-surgical or surgical. The latter is recommended, especially where an acute abdominal disease cannot be ruled out.

A brief review of the literature has been presented. One must always be aware of this condition in the differential diagnosis of the acute abdomen.

Anomalous Biliary Duct

A Case Report

GILBERT F. MUELLER, JR., CAPT. USAF (MC)
Minneapolis, Minnesota

Fig. 1.

RECENT literature concerning biliary tract surgery has emphasized the frequency of bile duct anomalies[1] and the serious, often fatal, consequences of the failure to recognize them at the operating table.[2] A plea for careful dissection and identification of all structures at the hilus of the liver is found in most articles dealing with the technique of gall bladder surgery. A case is presented of a rare and potentially dangerous anomaly of the biliary ducts encountered at the time of cholecystectomy.

Case Report

J. W.,* a twenty-one-year-old white woman, during the fifth month of a recent pregnancy first noted episodes of post-prandial, right upper quadrant pain which radiated to the back beneath the right scapula. The episodes of cramping pain lasted from two hours to several days. She vomited on occasion but never noted jaundice, dark urine or acholic stools. There was a definite relation of the attacks to fatty food ingestion.

Physical examination revealed a markedly obese woman weighing 201 pounds with right upper quadrant tenderness. There were no other unusual findings.

The pain was controlled medically by a combination of phenobarbital and belladonna and she was placed on a strict low fat diet in the Outpatient Clinic. Two cholecystograms and a subsequent intravenous cholangiogram failed to visualize the gall bladder. The attacks, though less severe, persisted, and nine months after the initial episode, she was subjected to surgery. She weighed 156 pounds when admitted to the Castle Air Force Base Hospital.

Exploration revealed inflammatory adhesions between the gall bladder and the duodenum. There were multiple small stones palpable within the gall bladder. Dissection at the triangle of Calot showed the common duct to be slightly enlarged, the cystic artery to be normal, and an anomalous right hepatic duct. Suspicion was first aroused when the apparent junction of the cystic and common duct appeared larger than usual, and even larger than the cystic duct near the neck of the gall bladder (Fig. 1). Further dissection demonstrated the actual cystic duct to terminate in an anomalous bile duct which entered the common duct. Cholangiograms performed through a polyethylene catheter inserted in the cystic duct confirmed the presence of the anomalous right hepatic duct and revealed a normal right and left hepatic duct (Fig. 2). The anomalous duct drained a minor portion (estimated 5 to 10 per cent) of the liver parenchyma. The cystic duct was ligated at its junction with the anomalous right hepatic duct, and the gall bladder removed. A common duct exploration was then performed and no stones or stricture were found. A T-tube was inserted in the common bile duct.

Postoperatively, the patient had considerable bile drainage on the dressings for twenty-four hours, but her abdomen remained soft, no jaundice was noted, her temperature remained below 100° F., and on the third postoperative day she was taking oral feedings and there was no drainage from the wound.

A cholangiogram done seven days after surgery again revealed the anomaly (Fig. 3). The T-tube was clamped and removed two days later. She was discharged on the ninth postoperative day.

Since discharge the patient has been entirely well, is eating all foods, and has had no abdominal distress.

This paper was written by Captain Mueller when he was serving as a surgeon in the Armed Forces. At present Dr. Mueller is a Surgical Resident at Minneapolis General Hospital.

*Reg. No. 28 327 Castle AFB Hospital.

Discussion

Failure to recognize the anomaly could have resulted in serious postoperative consequences. If the segment of liver drained by the accessory duct were large enough, a persistent biliary cutaneous fistula might have resulted following excessive hepatic drainage.

If the anomaly was not recognized until after the accessory duct had been mistakenly ligated at its junction with the common duct, an interesting circumstance arises. Should one attempt a primary anastomosis or ligate the anomalous duct proximally? Certainly, if this duct had been severed, its small size would almost doom to failure any first attempt at reconstruction of ductal continuity. Initially, ligation would be the best treatment. Serious consequence to ligation of an accessory duct of this size is not anticipated.* However, recent case reports from Johns Hopkins University[3] cite two examples of mild jaundice in patients with occlusion of the left hepatic duct by a calculus. Obstruction of a single hepatic duct due to postoperative stricture has also led to a low-grade jaundice in the experience of the Lahey Clinic.[4] No doubt, in this case, the liver would clear the blood of retained bilirubin from a minor segment as demonstrated by the cholangiogram. Should drainage of this segment become imparative at a later date, a second procedure would technically be more satisfactory. The ligated duct would be significantly dilated at this time and anastomosis of it to the common duct or bowel could be accomplished with less difficulty and greater assurance of continued patency.

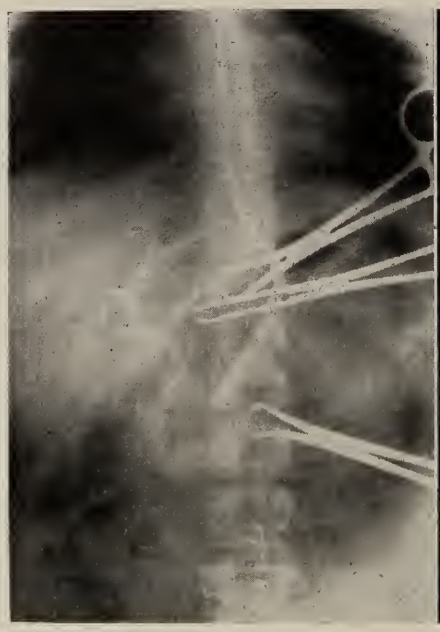

Fig. 2.

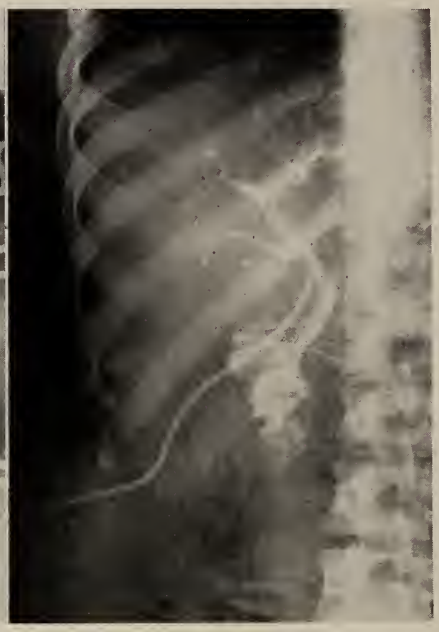

Fig. 3.

Conclusion

The biliary duct anomaly encountered in this case, namely an accessory right hepatic duct from which the cystic duct arises, is a rare bile duct variation. It is not recorded in texts on the subject and recent surveys. The occurrence of unusual variations in the extra-hepatic ductal system serves to emphasize the need for careful dissection and positive identification of all structures, both vascular and ductal, at the hilus of the liver before any single structure is ligated.

*Drs. Richard Cattell and John W. Braasch of the Lahey Clinic, who reviewed the case, concurred in these opinions.

THE PREDICTION OF WEIGHT LOSS ON A REDUCING DIET

Patients on reducing regimens frequently ask, "How fast will I lose on this diet?" It is often helpful to be able to make some estimate of the probable rate of loss, since many patients have exaggerated concepts of the rates of loss possible. It is important, however, to understand the variables involved in making such a prediction and to realize that only limited accuracy is possible.

In essence, any such prediction depends on knowledge of three factors, namely (1) the actual caloric intake, (2) the caloric expenditure and (3) the caloric value of the tissue lost during reduction. If these three factors are known, the rate at which weight is lost can be computed by simple arithmetic. The problem comes in knowing what values to assign to these three factors.

Caloric Intake

The caloric intake depends on the accuracy of measurement of the diet and the constancy of composition of foods. Even under the best of circumstances, there is probably an error of plus or minus 10 per cent in estimating caloric intake. This means that, even with the very best effort on the part of everyone concerned, the prescribing of a 1000-calorie diet may mean an actual consumption of something between 900 and 1100 calories. This does not consider the occasional excesses of food that must be expected of even the most conscientious dieter.

Caloric Expenditure

The caloric expenditure varies widely. Factors of age, sex, weight, height and activity and possibly the imposition of the diet itself all influence caloric expenditure. Of these, perhaps activity is the hardest to estimate. Some obese persons are exceedingly inactive, whereas others expend a great deal of energy in their work and in just getting about. In general, however, predictions that assume relative inactivity will prove most nearly correct. There is also the variable of the difference between the specific dynamic action of a maintenance diet and that of a reducing diet, although this should be rather small. This tends to decrease caloric expenditure as the individual begins the reducing diet and is an additional reason for making a relatively small allowance for activity in the computations to be described.

Caloric Value of Tissue Lost

The third factor, the caloric value of tissue lost during weight reduction, is difficult to estimate and apparently will vary somewhat with the duration of time from initiation of the reducing diet. It is a common observation by the dieting public that the first few pounds are lost easily and quickly but that sustained weight loss is slower and hence more discouraging.

Dole and associates[1] used the term "labile tissue" to describe that tissue lost during the first few days of a low-calorie diet. They stated that wet glycogen has a value of 1.72 calories per gram (cal./gm.) and "labile tissue protein" has a value of only 0.8 cal./gm. These figures are to be contrasted with the usually given values of 9.3 cal./gm. for fat and 4.0 cal./gm. for protein or carbohydrate. The initial rapid loss of weight on a reducing regimen is thought to be associated with decreases in body water, glycogen and labile protein, while later losses represent a greater proportion of adipose tissue.

The initial dehydration and rapid weight loss appear to be the result of the change from a mixed diet with a metabolic mixture derived mostly from carbohydrate to a metabolic mixture derived largely from endogenous fat. This idea is supported by observations of Holt[2] in infants and by calorimetric studies of Benedict and Milner.[3] Passmore and coworkers[4] suggested that the body may require 2 to 4 liters more of body water when metabolizing mostly carbohydrate than it does in metabolizing fat. This water might be partly extracellular fluid and partly fluid bound to glycogen and labile protein; the latter portion, therefore, might not be measured by dilution techniques.

Kekwick and Pawan[5] studied obese patients receiving diets composed in turn of 90 per cent fat, 90 per cent carbohydrate and 90 per cent protein for periods of five to nine days. The most rapid weight loss was found on the high-fat diet, and the

least occurred on the high-carbohydrate diet. While it is possible that the high-fat diet increased caloric expenditure, the differences in weight loss could well be the result of the factors already mentioned.

TABLE I. CALORIC VALUE OF "OBESITY TISSUE," AND FACTOR TO PREDICT WEIGHT LOSS

Authors	Source of Value	Cal./kg. of "Obesity Tissue"	Factor (Factor × Daily Caloric Deficit = Pounds Lost Per Week)
Strang and Evans[9]	Assumption that adipose tissue is 87 per cent fat and that weight accumulation is all adipose tissue	8091	0.0019
Wilder[7]	Assumption that adipose tissue is 86 per cent fat and that weight accumulation is all adipose tissue	7998	0.00193
Passmore et al.[4]	Observations on reducing patients, with careful estimates of caloric expenditure	7000-8100 (average of 7400)	0.0021
Keys et al.[6]	Forced feeding and weight gain in normal men	6180	0.0025
Taylor et al.[10]	Observations during first few days of starvation of normal men	2060-2598	0.0074-0.0064
Dole et al.[1]	Four-day periods of subcaloric diet alternating with four-day periods of generous diet	2510	0.0061

Other factors may influence hydration and thus cause variations in body weight from time to time. Emotional stress has been said to increase the retention of water, and release of such stress may result in diuresis and weight loss;[4] observations have not been extensive enough to say that such a relationship is constant, however. Rest in bed increases diuresis, and the additional possibility of retention of water on the basis of "starvation edema" during weight reduction is to be considered.

Thus, if the patient continues regularly on a diet, matters are complex enough, but if he eats an occasional carbohydrate meal in addition to his prescribed diet, he may temporarily accumulate an increment of "labile tissue" that causes a transient increase in weight out of proportion to the actual caloric value of the meal.

Despite the complexities of this problem, it is possible to make a clinically useful approximation of the over-all caloric value of tissue lost during weight reduction. Keys and associates[6] have clarified the problem by introducing the term of "obesity tissue" and defining it as the material laid down in response to excessive caloric intake; they regarded it as composed of fat, protein, other cellular solids and water, and not as simple adipose tissue alone. It is suggested that the muscle mass may increase in response to the increased load of moving a heavier body, and extracellular water (expressed in absolute terms rather than as percentage of body weight) has been shown to increase in developing obesity. Keys and co-workers estimated on the basis of feeding experiments that obesity tissue is composed of 13 to 15 per cent extracellular water, 0 to 1 per cent glycogen and 61 to 64 per cent fat, with the balance as "cells."

Wilder[7] used data from Bozenraad, who found that adipose tissue contained 15 per cent water by weight, assumed the balance was all fat, used a factor of 9.3 cal./gm. (the heat of combustion of fat) and derived a formula for predicting weight loss. Keys and Brozek[8] pointed out that computations for predicting weight loss based on Bozenraad's data assume that the difference between a thin man and a fat man is only in the amount of adipose tissue and ignore the possibility that muscle and extracellular fluid may increase with a gain in weight. The formula also assumes that adipose tissue is 85 per cent fat, the remainder being water. Keys and Brozek questioned whether such an assumption is justified, since Bozenraad's figures showed that adipose tissue contained an average of 15 per cent water but did not give a direct analysis of the fat.

Some of the estimates of the caloric value of obesity tissue are given in the accompanying table. It is notable that the two estimates giving a relatively low caloric value are for brief periods at the beginning of caloric restriction and would correspond to "labile tissue." The agreement between the first four values is surprisingly good, perhaps good enough to permit some prediction of the probable rate of weight loss. The error in estimating probable caloric expenditure is likely to be appreciably greater than the minor differences between the several values given for the caloric content of obesity tissue.

How to Predict Loss of Weight

The caloric expenditure can be estimated by means of the Boothby-Berkson nomogram,[11] using the measured height and a weight about 20 pounds less than that at the beginning of the period of observation. This smaller weight is chosen because

it should reflect more accurately the weight of the patient during the period of weight loss than would the initial weight, although the difference in the final results using the two different weights is relatively small. An increment of 30 per cent of the basal requirements usually is added to provide for ordinary activity, but a smaller or larger value should be substituted if activity is greatly different from average light housework or desk work. The difference between the caloric expenditure and the caloric content of the diet prescribed multiplied by the factor 0.002 will then yield the prediction of pounds per week likely to be lost. It is emphasized that this prediction is subject to many variables and should be regarded as only a gross approximation. If considered in this manner, this factor may be a clinically useful figure.

CLIFFORD F. GASTINEAU, M.D.

ON GROWING OLD

Almost everyone has heard Maurice Chevalier sing in Gigi, "I'm glad I'm not young anymore." I can echo that sentiment. We have learned that, with all its joys, youth has its deep sorrows too, without the years of experience to temper them. When one gets old, both joys and sorrows are weighed relatively, thereby missing the depths and not quite scaling the heights but reaching acceptance and sometimes serenity.

When my father was eighty, he said one day, "My girl, it seems just yesterday I was planning my life, and now it is almost over and the past is like a dream." I know what he was talking about, although I didn't at the time. If we have lived fully while growing old, age itself has few terrors. The one which is on the border of consciousness is that of chronic or disabling illness. Since that is out of one's control, the farther back it can be kept the better.

A small percentage of people have no interests outside themselves. As their world contracts with a family gone, a job over with, friends dying, their plight is sad. More and more communities are providing some public leisure time activities hoping that through advertising, through word of mouth, or even through desperation, the people who now need to make new friends will utilize the opportunities presented.

Dr. Walter Gardner has said that in old age you are just what you were when young—only more so. If activities through PTA, through business associations, through clubs, or most of all through volunteer work in civic or social agencies have been part of your life, then the later years are bound to be fuller than you could anticipate.

I have had a wonderful life. I was able to carry my professional experience into volunteer work at once. My husband was proud to have me able to be of service. My children probably thought I went to too many meetings. But now, when I am alone they, too, are proud that I have so much to do. I have no time to look backward regretfully, but can look forward to the next meeting, the next project, or the next assignment with anticipation.

Many people have had happy church connections sometimes on the receiving end rather than the giving. The later years give time to be available for the duties someone has to do. There are envelopes to stuff, food to prepare, bazaars to man, telephoning to be completed. Some churches are setting up clubs for older people to which the community is invited, not just the congregation. A member of the congregation could help start such a group if she felt dedicated enough. Otherwise another dedicated one has to search out the re-

tiring one and try to make her future outlook happier by a closer renewed interest in her church.

I like some fields of art. There are endless opportunities if your community has an art institute or art school. Each one will have different projects but willing hands are always needed. This is equally true of little theatres, or science museums, or historical societies, who need work done and seldom have money enough to hire all the services which are needed. If you have a deep interest and are otherwise qualified you are apt to find yourself a board member which carries a great reward for work done.

Bridge, canasta, or other card games are such sociable activities they can't help but make a day seem brighter. If you can serve coffee and a doughnut, it becomes a party. In one room or ten the hospitality can be offered. It can be offered without the game. In our neighborhood, we often have a delightful coffee klatche, and it's the conversation we enjoy—just getting together.

In low moments which come to us all, we can't forget the joy found in walking, with due concern for the slippery weeks in our lovely state. A good brisk walk, alert to the sky, the branches of trees, later the leaves, give one rising spirits and comfortable nights.

No age is without its trials, each decade has its special joys. This is just as true of the sixth decade as it was of the first. More and more of us are living longer and longer in this terrifying but magnificent age. We are fortunate to be part of it, and owe it our service.

Governor's Citizen's Council on Aging

IONIZING RADIATION HAZARDS

A Perspective

The recent report to the surgeon general of the U. S. Public Health Service prepared by the National Advisory Committee on Radiation concludes that the cost of an adequate radiation control program by the Federal Government "will reach a level of approximately fifty million dollars in a period of five years." Perhaps no other single statement so aptly portrays the growing concern by responsible medical and public health officials regarding the rapid increases of the population's exposure to all forms of ionizing radiation.

Fallout from nuclear weapons testing has been the subject of much public controversy, and indeed there is sufficient evidence for justifiable serious concern over this problem. Nonetheless, viewing the lifetime exposure of the whole body for the general population from all sources of ionizing radiation, most estimates are in the range of about 30 per cent from natural background, less than 5 per cent from fallout, and about 65 per cent as a result of the health professions' use of x-rays. The steady increase in the use of x-ray is shown by the following table of the annual whole body dose of radiation received by an average individual of the United States from x-ray sources. This upward trend is expected to continue.

Year	*Dose in Millirems*
1925	15
1935	40
1945	75
1955	135

Other major sources of exposure to ionizing radiation created or developed by man include nuclear reactors, their radioisotopic by-products, concentrated naturally occurring radioactive materials, and high energy particle accelerators. It is currently estimated that in 1965 there will have accumulated 1,500,000 gallons of high and intermediate level radioactive waste products from nuclear power development, and that by 1995 this volume will be 2,900,000,000 gallons. To what extent these wastes will add to the increasing burden of exposure to the general population is unknown. At the moment, it can be fairly stated that safe and adequate disposal methods for these quantities of wastes are not available.

The present use of radioisotopes in medicine, research, and industry is visualized as only at the threshold of probable development. The growth of the use of these materials is demonstrated by the annual shipment records for radioisotopes from the Oak Ridge National Laboratories as follows:

Year	*Curies shipped*
1952	12,000
1954	30,000
1956	100,000
1958	230,000

While this growth, in itself disturbing, in the use of devices and materials which produce ionizing

radiation has been gaining momentum, the maximum permissible levels of exposure to ionizing radiations as established by the National Committee on Radiation Protection and other authoritative groups have been successively and drastically revised downward during the last thirty years. The maximum permissible annual dose for workers occupationally exposed to ionizing radiation has been reduced, in the last year, from 15 rem to 5 rem, and the equivalent permissible dose during the period of 1931 to 1936 was 60 rem.

It is evident that serious health hazards can be anticipated unless strong and aggressive safeguards and controls are developed and applied to limit undue radiation exposure by every practical means, not only for the population at large, but also individual by individual. Any and all exposure, in final analysis, is undesirable. Practically, the ideal of no exposure from any source is unattainable. Further increases of exposure levels are undoubtedly inevitable, if advances in technology and science are to continue. The decision of just what constitutes an acceptable sacrifice of the public health for the potential human benefits to be derived in the nuclear age will eventually have to be faced.

F. L. Woodward
Minnesota Department of Health

MEDICAL PRACTICE PLANNED BY STUDENTS

The type of practice planned by senior medical students is affected by marital status to a larger extent for males than for females. Specialty practice is planned by almost three-quarters of the single men; by about two-thirds of the married men with no children, and by little more than half of the married men who had children. This decrease by marital status in the proportion of men choosing specialty practice is accompanied by an increase in each category respectively, in the proportion of men favoring general practice.

Marital status seems to be a less important factor with female than male students in choosing the type of practice. It is interesting to note that specialty practice is preferred by a somewhat larger proportion of women with children than by women who had no children.

HOW TO WRECK A MEETING

"How to Wreck a Meeting" is the title of a tongue-in-cheek article which recently appeared in the American Management Association's publication, *The Management Review.*

The article offers the following advice on how *not* to use a meeting to good advantage:

To the Chairman: (1) Call the meeting without notice. (2) If you have compiled 10 pages of advance information that was sent to everyone, read it aloud and explain the footnotes. (3) Squelch any new approach not outlined in the agenda. (4) Let Sam and Joe debate their personal differences for the length of the meeting, thus providing good clean entertainment for all. (5) Or, insist that Sam and Joe are really in agreement, and prove it by misquoting them. This will unite them in an attack on you. (6) Change the decisions reached at the meeting—but don't let others know (it might hurt their feelings).

To the Participants: (1) Let the chairman do all the work. It's his meeting. (2) Defend yourself! Anyone who openly disagrees with your viewpoint probably has it in for you. (3) Take careful notes on everything, including date, time, temperature and barometer reading. If you don't catch every word that's said, ask for a recap. (4) Don't listen to others; they will only confuse you. Use the time while they're talking to think up your next remarks. (5) Side with the majority, regardless of your real opinion.

President's Letter

DOCTOR IS OUT

"He is attending the 107th Annual Meeting of the Minnesota State Medical Association, where he is hearing lectures by the leading scientists of the nation and viewing the latest medical and surgical techniques and equipment that he may better serve your medical needs."

This message posted in your office May 23, 24 and 25, will inform your patients that your brief absence to attend the Annual Meeting of our State Association is in their best interest.

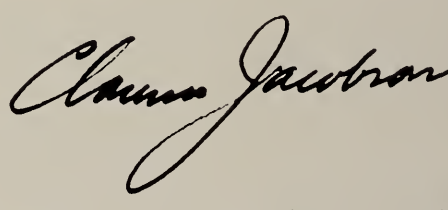
To you, as members, we extend a cordial invitation as well as a gentle exhortation to attend all scientific sessions in the Mayo Civic Auditorium. We remind you also of the important contributions which our technical exhibitors annually make toward the over-all success of the meeting.

The opening session of the House of Delegates will convene Sunday, May 22, at 2:00 p.m.

An entire day of Symposiums on Rheumatic Heart Disease and Diseases of the Lung is scheduled for Monday the opening day of general scientific sessions. Other program highlights for Monday include a lecture on Space Medicine by A. H. Schwichtenberg, M.D., Albuquerque, New Mexico; and the Arthur H. Sanford Lecture in Clinical Pathology to be given by Tague C. Chisholm, M.D., Minneapolis. "The Acutely Burned Child" will be the topic of Doctor Chisholm's address. The final scientific session scheduled for Monday will feature a Clinical-Pathological Conference on Diseases of the Chest.

Scientific sessions on Tuesday will be devoted to cancer. A Symposium on Cancer Detection for Practicing Physicians has been set for 9:00 a.m.

Joseph H. Ogura, M.D., St. Louis, Missouri, will give the Minnesota Academy of Ophthalmology and Otolaryngology Lecture on "Cancer of the Throat" at 11:00 a.m.



"The Meaning of Curative and Palliative Radiation Therapy" will be discussed by Walter T. Murphy, M.D., Buffalo, New York. Also included in the Tuesday series of presentations on cancer will be two Symposiums on Cancer Treatment and Management of the Far-advanced Cancer Patient.

The Wednesday morning session will be a novelty. It will be devoted entirely to a series of six dry clinics by Mayo Clinic staff members on pertinent topics, all at the Auditorium.

All physicians and their wives are invited to be guests of the Zumbro Valley Medical Society, Monday, May 23, at 9:00 p.m., at the Mayo Civic Auditorium for the annual open house.

We have been fortunate in securing as our annual banquet speaker, Dr. Laurence Gould, President of Carleton College in Northfield. "Education for a World of Change" will be the title of Dr. Gould's address.

You will like to attend the meeting in Rochester because the program is first class, housing accommodations are excellent, parking facilities are good, the exhibits and meetings will be held in a modern setting, and Minnesota physician fellowship will be at its best. Check the Preliminary Program in this issue of MINNESOTA MEDICINE, as well as the Official Program which you will receive, for full program details.

Convention City

Rochester, a city rich in history, was settled in the early 1850's by men who recognized its potential as an agricultural center. After the turn of the century, fate made it a world center of medicine. Today it is a bustling city of many pursuits.

Rochester, county seat of Olmstead County, is situated in the heart of southern Minnesota's rich agricultural and dairying section, approximately 75 air miles southeast of Minneapolis and St. Paul.

Rochester was founded in 1854 as a crossroads campground for wagon trains that were pouring into Minnesota. From a population of less than 50 in 1856, it has grown to become a city of 36,000 residents, with a transient population annually of 350,000.

Rochester is a fascinating combination of industry, commerce, fine homes and cultural institutions in the midst of an agricultural region.

Friendly Rochester combines the intimate congeniality of a small city with the advantages of a metropolitan center. Its services attract hundreds of thousands of people from nations around the globe. The result is a cosmopolitan atmosphere and activities ordinarily found only in much larger cities.

Some industry Rochester has developed because of its medical aspects and some because of its location in an agricultural area. Large dairy concerns are situated here. Other industries related to agriculture operate in the community. With the decision of International Business Machines corporation to establish a large and important phase of its operation on a 397-acre plot at the city's edge a new horizon of industry was opened for Rochester. Thus it becomes a community dedicated to alleviating both man's ills and his toils.

Rochester Welcomes You

MAYO CLINIC—Out of a quest for greater knowledge of man's ills and their treatment and the idea of combining the minds, skills, and experiences of many doctors grew the now famous Mayo Clinic. It is a voluntary association of physicians—largest of its kind in the world. Yet it owns or operates no hospitals, buildings or real property. The buildings which house the Mayo Clinic are owned by the Mayo association, a non-stock, non-profit, charitable and educational organization. Much of the effort and many of the facilities of Rochester's medical colony are dedicated to education and research. The huge Medical Sciences building exists for these purposes alone. Much of the work is carried on by Fellows, graduate medical students enrolled in the Mayo Foundation for Medical Education and Research, which is a branch of the University of Minnesota. The Mayo Clinic has a permanent staff of 330 doctors. Fellows enrolled in the Mayo foundation number another 570 for a total of 900 doctors.

MAYO MEMORIAL—Rochester pays tribute to the men who developed a medical history as thrilling as it is amazing through the Mayo memorial. It is a formal mall with a statue of Dr. W. W. Mayo (1819-1911) at one end with the Mayo Clinic tower in the background. At the other end are bronze statues of his two sons, Dr. "Will" (1861-1939) and Dr. "Charlie" (1865-1939) overlooking a marble amphitheatre symbolic of an operating room.

AUDITORIUM—The center of much Rochester activity is spacious, modern Mayo Civic auditorium, where everything from symphony concerts to cattle shows and from hockey to road shows is staged. The very flexible arena seats up to 6,000, the beautiful theater section, up to 1,500, and auxiliary meeting halls up to 400. It is air-conditioned throughout.

George Earl, M.D., Chairman

THE AMA RECORD VERSUS "POLITICAL MEMO FROM COPE"

The AFL-CIO Committee on Political Education (COPE), on February 1, 1960, published a political memorandum entitled "The Forand Bill and the Record of the AMA." The memorandum consists of sixteen charges purporting to show that the American Medical Association has opposed beneficial health measures. The memorandum suggests that the Association's opposition to the Forand Bill is another example of this so-called "reactionary" attitude.

Although the COPE statement cites no references, it is taken almost word for word from a a campaign speech delivered on October 27, 1950, by former Congressman, Eugene D. O'Sullivan, from the Second Congressional District of Nebraska. After losing his campaign for re-election, Congressman O'Sullivan had the speech printed in the Congressional Record of December 8, 1950.

The memorandum contains so many falsehoods and distortions that AMA's President, Dr. Louis M. Orr, has demanded a retraction of the statements. The demand for a retraction and a factual explanation of the Association's position on the health measures mentioned in the COPE memo were contained in a letter written by Doctor Orr on March 15, 1960, to George Meany, President of AFL-CIO.

Following are the allegations and the facts:

Allegation

1. *"A generation ago, the AMA opposed the requirement that all cases of tuberculosis be reported to a public authority—the foundation for all tuberculous control methods."*

Facts

The AMA has not opposed reporting cases of tuberculosis to a public authority.

The history of the Association's interest in the control of tuberculosis can be traced back to 1899, when the House of Delegates appointed a Committee to report on the nature of tuberculosis, means of control, public education and the advisability of establishing national and state sanitariums.

The most recent AMA action on this subject was in 1944 when a resolution on the control of tuberculosis was approved. It stated in part "that it is necessary to extend procedures for careful, continuous supervision of the tuberculous by practicing physicians, who, in cooperation with duly constituted health authorities, federal, state and local, are in a position to deal with these problems by modern methods to prevent the spread of this communicable disease."

Allegation

2. *"The AMA opposed the National Tuberculosis Act a week before Congress passed it unanimously."*

Facts

Although the House of Delegates was in sympathy with the purposes of the proposed National Tuberculosis Act, it opposed the bill for the following reasons:

(1) Money could not be appropriated or expended for the purposes of the legislation without the approval of the Federal Security Agency.
(2) The objectives of the legislation could be obtained in other ways, as for example, direct aid to needy communities under the Lanham Act.

Allegation

3. *"The AMA fought compulsory vaccination for smallpox."*

Facts

This statement would be accurate if it said: The AMA fought *for* compulsory vaccination for smallpox because in 1899, the House of Delegates adopted a resolution which urged local boards of health to adopt laws requiring compulsory vaccination for smallpox.

Allegation

4. *"The AMA attacked provisions for immunization against diphtheria and other preventive measures against contagious diseases by public health agencies."*

Facts

The AMA has not only cooperated with public health agencies for the prevention of contagious

diseases, but also has made many recommendations for affirmative action in this field. The following are only a few examples of AMA activity:

(1) From 1875 to 1879, the AMA urged "that state boards of health be established in those states where such boards do not exist."

(2) In 1884 it recommended that Congress "make suitable appropriations for the prosecution of scientific research relating to the cause and prevention of the infectious diseases of the human race," and also in that year passed a resolution that "it is important that proper legislation be had at this session of the National Congress for the ultimate extermination . . . of pleuropneumonia."

(3) In 1907 the Committee on Legislation was requested by the House of Delegates to take the necessary steps to secure national and state legislation for control of rabies.

(4) A report adopted by the House of Delegates in 1950 read in part, as follows: "The basic services of the department of public health should be . . . prevention of disease and control of communicable disease such as the diseases of childhood, venereal diseases and tuberculosis."

Allegation

5. *"The AMA opposed the first bills to grant Federal aid to the states to reduce infant and maternal deaths."*

Facts

In 1922, the AMA opposed the Sheppard-Towner Maternity and Infancy Act, which authorized the payment of subsidies to the states over a fixed period of years because it believed that each state should be left free to formulate its own maternal-infant welfare programs with the cooperation of the United States Public Health Service and that any legislation involving cooperation between the federal government should be jointly administered by the USPHS and state health authorities.

Allegation

6. *"The AMA opposed the Social Security Act, passed in 1935."*

Facts

The AMA has never taken a position on the retirement provisions of the Social Security Act.

Allegation

7. *"In 1939, on behalf of the AMA Board of Trustees, Doctor Morris Fishbein condemned old-age and employment insurance as a 'definite step to either communism or totalitarianism'."*

Facts

The quotation attributed to Doctor Fishbein is taken out of context. In November, 1939, Doctor Fishbein, who was then Editor of the *Journal of the American Medical Association,* addressed the Annual Conference of Secretaries of Constituent Medical Associations on the AMA's position on health legislation. He said, "We are asking the government to go forward with the medical profession in attaining a wider distribution of medical and preventive services based on actually demonstrated needs of various communities . . ." He then went on to discuss medicine's plans for achieving this result and some problems which had resulted from the construction of facilities by the federal government where there was no demonstrated need. The only reference to social security occurred in the conclusion of the speech:

> "The introduction into this nation of a federal security plan whereby the national itself, as a federal agency, will step intimately into the sickness and life of every person in the country, will be the first step in the breakdown of American democracy. Indeed, all forms of security, compulsory security, even against old-age and unemployment, represent a beginning invasion by the state into the personal life of the individual, represent a taking away of individual responsibility, a weakening of national caliber, a definite step toward either communism or totalitarianism."

It is clear that the subject of Doctor Fishbein's remarks was health care, not social security. Even his one reference to social security showed more concern over the possible future consequences of compulsory programs than antagonism toward the old-age and unemployment insurance program. Since the AMA did not oppose old-age and unemployment insurance, it is difficult to see what this COPE allegation is trying to "prove."

Allegation

8. *"The AMA opposed the creation of public venereal disease clinics."*

Facts

The AMA has fought venereal disease as it has other diseases which have threatened the American public. In 1907, it resolved "that it should be the duty of state boards of health to disseminate literature . . . to educate the people on the subject of venereal disease." Other actions have included:

(1) Cooperation of the American Medical Association with the United States Public Health Service for better control of venereal disease.

(2) Statements that the medical profession should cooperate with the official health agencies charged with the responsibility for an expanded program for the control of venereal diseases that has been made possible by federal grants-in-aid.

(3) A twelve-point program for improved medical care which included "Establishment of local public health units and incorporation in health centers and local public health units of such services as . . . control of venereal diseases . . ."
(4) Approval of the treatment of nonindigents for venereal disease by public health clinics in instances when such treatment is not available through private sources.

Allegation

9. *"The AMA opposed the creation of free diagnostic centers for tuberculosis and cancer."*

Facts

In 1948, the House of Delegates approved a resolution which authorized the Association to cooperate with the American Cancer Society and other agencies engaged in cancer detection "for the purpose of formulating standards of procedure and conduct in the operation of cancer detection and diagnostic centers and that the results of these studies be adequately publicized to those concerned, including the medical profession and the public."

As part of its program for improved medical care, the AMA approved the diagnosis of tuberculosis by the treatment of indigents by public health centers. In addition, it approved the treatment of nonindigents by these centers if treatment is not available through private sources.

Allegation

10. *"The AMA fought the American Red Cross plan to set up a nation-wide reserve of civilian blood banks."*

Facts

The AMA, instead of fighting the Red Cross plan for blood banks actively supported such a plan. This consistent approval is shown by the following actions:

(1) 1947—approval in principle of the American Red Cross Plan establishment of a national blood program.
(2) 1949—the AMA statement that there was an urgent need for a national blood program and that the Red Cross was the logical agency to assume the responsibility for such a program.
(3) 1953—the House of Delegates urged the establishment of a coordinated national blood bank program to be organized by the AMA, American National Red Cross, and other qualified organizations.
(4) 1954—the AMA adopted a plan for a national blood program which was developed and unanimously approved by representatives of the American Red Cross, the American Hospital Association, the American Association of Blood Banks, the American Society of Clinical Pathologists and the Committee on Blood of the American Medical Association.

Allegation

11. *"The AMA opposed Federal aid to medical education even after AMA representatives had testified before Congress that the medical schools were in dire financial emergency, and that there was a serious shortage of doctors in the U. S."*

Facts

The AMA would prefer to see necessary support for medical education received from private philanthropy or local public funds. However, it is recognized that until such support is provided, federal aid may be necessary if the legislation guarantees absolute freedom of medical education under government control.

In 1951, the Association endorsed the principle of one time grants-in-aid based on the Hill-Burton formula for the construction, equipment and renovation of the physical plants of medical schools. The funds were not to be used for operational expenses or salaries. This position has been reaffirmed by the House of Delegates several times.

The AMA has opposed bills for federal aid to medical education which did not guarantee freedom of medical education and which would have provided funds for salaries.

Allegations

12. *"The AMA attacked voluntary health insurance plans as 'socialism, communism—inciting to revolution.' (ho, hum.)"* and
13. *"It dismissed Blue Cross as 'a half-baked scheme'."*

Facts

The first quotation is taken out of context. It is from an editorial in JAMA of December 3, 1932, concerning two reports of a Committee on the Cost of Medical Care. The majority report urged medical practice by organized groups of physicians associated with hospitals. Commenting on this, the *Journal* said: "The alignment is clear —on the one side, the forces representing the great foundations, public health officialdom, social theory—even socialism and communism—inciting resolution; on the other side, the organized medical profession of the country, urging an orderly evolution." It should be noted that this same editorial referred to health insurance as "foresighted, American, economical."

The second quotation does not even mention Blue Cross. It is from a *Journal* editorial of March 25, 1933, which criticized the attempts of some individuals to make large profits from health insurance. The AMA has never opposed the development of voluntary sickness insurance plans in this country as they exist today.

Allegation

14. *"The AMA opposed school health service legislation."*

Facts

This statement apparently refers to testimony given by the AMA on H.R. 3942 81st Congress. Our witness stated that the Association was in agreement with the general purpose of the bill and considered it so worthwhile that we would not oppose it if we did not feel that, in its present form, it would fail to accomplish its purpose. It should be remembered that there is a great deal of difference between opposing the principles of a particular type of legislation and opposing an ineffectual bill.

Allegation

15. *"The AMA fought federal aid to public health units."*

Facts

The following statement, which reflects the AMA's position in regard to this subject, is taken from testimony given before the House Interstate and Foreign Commerce Committee on July 6, 1949: "We, the American Medical Association, have long believed that the existence of . . . public health units is basic to the maintenance of and improvement of the health of our people. Recognition of this conviction was reflected in action taken by the Association as early as 1883, when a report was made at our annual meeting for that year covering a survey conducted to ascertain what states and counties had at that time health departments." The AMA has not opposed aid to public health units, but has suggested amendments which would define the term "public health" as used in the proposed laws and which would exclude care of the sick.

Allegation

16. *"The AMA blasted a Defense Department request to Congress to give Government medical care to dependents of men in the Armed Forces, with particular reference to the men then fighting in Korea as 'unpractical and harmful to National Defense'."*

Facts

The AMA testified on H.R. 7994, 84th Congress, which became the Dependent Medical Care Act and in this testimony stated:

"As you know, on the basis of our previous testimony, the American Medical Association has taken no position on the question of whether it is the responsibility of the government to provide medical care for the dependents of military personnel. In our opinion this is a question for Congress to decide. We do strongly urge, however, in the event such care is to be provided, that increased emphasis be placed on the utilization of civilian facilities and the services of civilian physicans."

The quotation in the allegation does not appear in the testimony or in any statement of AMA policy. In fact, the House of Delegates, when expounding its policy on medicare, specifically stated: "The policy advocated should not in any way be construed as one of opposition by the American Medical Association to dependent medical care; . . ."

CARE COVERAGE FOR THE AGED

Health Insurance companies are demonstrating effectively their capacity for providing medical, surgical, and hospital care coverage for older people, Robert R. Neal, General Manager of the Health Insurance Association of America, said recently.

Rapid Development of "Over Sixty-five" Plans Noted

Mr. Neal, speaking in Washington, D. C., during the annual meeting of the American Association of University Teachers of Insurance, emphasized that the insurance carriers are making rapid strides in developing and offering health insurance programs specifically designed for people age sixty-five and over. Among the plans offered to older persons who want assistance in meeting their health care expenses, he named the following:

"1. Continuation of insurance on older active workers under group insurance plans.

"2. Continuation of group insurance on retired workers and their dependents, generally with part or all of the premium paid by the employer.

"3. Continuation on an individual-policy basis of coverage originally provided by group insurance.

"4. New issuance of group insurance at advanced ages.

"5. Continuation into the later years of individual insurance bought in the productive years.

"6. New issuance of individually-purchased policies at advanced ages.

"7. Issuance of insurance that becomes paid-up at age sixty-five."

Many health insurance companies have been writing policies in line with or similar to these plans for some time, Mr. Neal brought out. The companies, he said, are gearing their efforts to the need for providing more and better coverage at a cost which the public can pay. Looking to the future, Mr. Neal added:

"It is reasonable to assume that within a few years most private health insurance carriers will have acted to eliminate the older policyholder's anxiety that his coverage will not be renewed when he reaches age sixty-five. Moreover, it can be expected that coverage of persons over age sixty-five will increase more rapidly in the future."

Government Interest in Insurance Field Increases

The growing complexity of the social and economic consequences of health insurance has been attended by increasing Federal Government interest in the operations of insurance companies. As recent evidences of the extent of Federal activities of considerable concern to the insurance business, Mr. Neal listed these actions: The creation of the Senate Labor Subcommittee on problems of the aged and aging, and the public hearings held this year by that group; the introduction of the Forand Bill, H.R. 4700, which would append health insurance to the Social Security program; and congressional authorization of the White House Conference on Aging, to be held in January, 1961.

Dangers of Government Health Insurance Explained

There is a very real danger, the HIAA official pointed out, of Federal intervention in the field of health insurance. He told his audience:

"Should that intervention occur, the Government would take over a large and important area which has been the responsibility of the enterprise system. Obviously, the establishment of Federal administrative machinery to operate health insurance programs could possibly be the forerunner of government intervention in other fields of insurance. Workmen's compensation, the casualty lines, and life insurance could and would likely become targets of further Federal encroachment."

Mr. Neal summed up the position of the health insurance business, as regards possible national government intervention in health insurance operations, in the following terms:

"Admittedly, the issues involved are broad, and it is not easy to deal with them. The main objective to be served is the public interest. The basic issue, then, is whether the voluntary system, which has achieved so much for so many millions of people in so short a span of years, is to be permitted to demonstrate that it can and will continue to serve the public interest with greater effectiveness and at lower cost than can the cumbersome, rigid, and expensive methods which would be employed by those who advocate governmental intervention."

LOW DRUG PRICES MAINTAINED DURING INFLATION, SENATE INVESTIGATORS TOLD

"Americans would be paying a billion dollars a year more for drugs if the price of medicine in the past few years had gone up only as much as the total cost of living." Dr. Austin Smith, President of the Pharmaceutical Manufacturers Association, told Senate investigators.

He said the drug industry has "an outstanding record of low prices maintained in an inflationary period." Doctor Smith testified before the Kefauver Anti-Trust Committee in rebuttal to the Senator's criticisms of industry practices.

He declared, furthermore, that "on the basis of the record," he knows of "no other American industry that has contributed more from its resources to the public welfare."

Life Span Increased by New Drugs

Modern drugs have helped to add nearly ten years to the lifespan of the average American within the past thirty years, he observed, adding: "since 1947 this industry has spent about $1 billion in research alone."

He said the pharmaceutical industry has served the public interest by driving prices down to the lowest possible levels.

Scoring earlier criticism of industry prices, he said there is "grave danger of misinforming the public when attention is directed toward the single product of a single company . . . without relating these to the many thousands of products produced by the entire industry."

Competition Is Healthy

Doctor Smith declared that the competitive pharmaceutical industry in America "has played a role unparalleled elsewhere in the world in reducing human suffering and in helping to eradicate diseases which have crippled mankind for centuries."

Citing the lack of inventiveness in drugs within the Soviet Union, he emphasized that "there has been no missile gap in pharmaceutical research."

Recalling major breakthroughs attributable in significant ways to U. S. drug industry laboratories, Doctor Smith named the discovery and development of the sulfa drugs, the synthesis and discovery and development of high-potency corticosteroids, the mass production of penicillin, and

the discovery and development of the other broad-spectrum antibiotics.

Research Risks Noted

Emphasizing the "staggering investment" which the drug industry puts into research, Doctor Smith said that "the chance that any given research involving a new potential medicine will be successful stands at 2,865 to one against the manufacturer."

He said the industry's research resulted in valuable palliative treatment for cancer, and that the industry was also responsible for the discovery and development of tranquilizer drugs for treating mental illness, oral diabetic drugs, and the hydrazide derivatives for treating tuberculosis.

New Drugs Save Dollars

Doctor Smith said that every major advance of the U. S. drug industry has been accomplished by "astronomical dollars-and-cents savings to the American people."

He said that vast reductions in medical expenses were made possible by rapid cures for illnesses and by the shorter length of hospitalization which results in increased productivity of those to whom new drugs have made cure possible.

Doctor Smith said that this has also meant "mammoth tax savings to the public" by reducing the cost of public health services.

The drug industry official took issue with the committee for airing opinions of individuals critical of the industry without hearing from persons who represent "unquestioned authority."

He cited statements by Dr. James Watt, Director of the National Heart Institute, and Dr. Robert H. Felix, Director of the National Institute of Mental Health, crediting the drug industry for development of important medicines in these fields.

Benefits of Modern Chemotherapy Noted

He said that modern chemotherapy "permits a physician to treat many specific organs, and to conquer many specific diseases, with the precision of a surgeon using a scalpel." Listing some of the benefits of medicine within the past two decades, he said:

"More than 3,000,000 Americans, living today, would be dead if the nation's death rate had remained constant at its 1937 level.

"Between 1930 and 1958 the death rate for babies under one year was cut 57 per cent—for children one to four years, was reduced 80 per cent—for children five to fourteen years, was reduced 71 per cent.

"Only as recently as the years 1930 to 1934, one of every 157 mothers died at childbirth. From one out of 157, this number was slashed to one out of 2,222 in the four years ending in 1958.

"In the past thirty years alone, modern drugs have helped add nearly ten extra years to the U. S. lifespan."

MINNESOTA GOP TAKES ANTI-FORAND STAND

The Minnesota Republican Welfare Advisory Committee recently issued a statement opposing the highly controversial Forand Bill on the grounds that old age medical assistance can be and is being more adequately handled at the state level.

"The Minnesota Old Age Assistance medical program is much more complete than that provided in the Forand Bill, because we give complete medical, drug, surgical, hospital, dental and nursing home care," the GOP committee stated in a resolution being sent to Republican district conventions.

"Under a Republican state administration in 1945, maximum limits were removed on all types of medical care for the aged. Ever since 1945, Minnesota has through its old age assistance medical program met the needs of aged people much more fully and adequately than is true in most all other states.

"Under the Forand Bill, citizens of Minnesota would be called upon to send thousands of dollars out of the state to pay for medical assistance in states which have failed to come to grips with their own problem."

In support of the committee resolution, GOP State Chairman Ed Viehman termed the Forand Bill an "invitation to federal socialized medicine."

"We want to take care of our own problems in this important field, and other states should be encouarged to do likewise," Viehman commented.

The advisory committee, formed to advise the draftees of the welfare plank of the 1960 Republican platform, pointed out that the Forand program is limited in its coverage.

"It would provide a maximum of 120 days of hospital care and nursing care in any twelve-month period.

"It would not provide the type of medical care that is customarily needed by older people, such as is rendered by thousands of general practitioners throughout the state. On the contrary, it is primarily limited to surgical care in certain hospitals.

"Older people need medical care in their own homes, in nursing homes or community hospitals or doctors' offices.

"The people of America, as well as members of Congress, need to know more about the problems of the aged before this major legislative step is taken."

Pointing out that a White House Conference on Aging is scheduled for early next year to consider these matters, the committee urged that action on the bill be postponed until after the results of that conference are known rather than to enact a "stop-gap" plan at this session of Congress.

OPTOMETRISTS SEEK NEW DEFINITION OF "MEDICAL SERVICES"

The House Committee on Veterans Affairs has endorsed H.R. 7966 to amend the definition of "medical services" in Section 601 (6) of Title 38, U. S. Code, to include services of optometrists.

Effect of this legislation is to classify optometric services as "medical services" and provide Federal compensation of optometrists for out-patient care given veterans with service-connected conditions.

Favorable House action is likely unless strong protest is registered.

According to analytical comment by the National Medical Foundation for Eye Care, "medical services" should be rendered by medical practitioners. The optometrist is not a medical practitioner.

To classify optometrists among those qualified to render "medical services" implies that they are qualified and authorized to diagnose and treat eye diseases. This constitutes the practice of medicine.

Veterans with service-connected conditions are entitled to the highest quality of medical care. To grant optometrists the right to perform eye examinations may result in failure to administer necessary sight-saving medical treatment and rehabilitative care.

Determination of service-connection requires a medical judgment; and the further decision, whether refraction and glasses are needed as part of the medical treatment, cannot be made until after a diagnostic examination by a medical practitioner. These medical services cannot be rendered by optometrists and it would seldom be feasible, economical or in the best interests of the patient to transfer the patient from the medical to the non-medical practitioner for a portion of the medical eye care required.

CORRECTION

Readers are requested to correct the wording in the next to the last paragraph in Civil Defense News, page 140, in the February issue, wherein the word "Michigan" was printed in error. The sentence should read "The *Minnesota* State Medical Association has been very active in Civil Defense."

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

ST. PAUL PAINTER SENTENCED FOR BASIC SCIENCE VIOLATION

On January 15, 1960 John Petschon, thirty-three, 613 N. Grotto St., St. Paul, was sentenced by the Hon. Levi Hall, Judge of the District Court of Hennepin County, to a term of one year in the Minneapolis Workhouse on a charge of practicing healing without having a basic science certificate. Judge Hall then suspended the sentence and placed the defendant on probation for one year under the supervision of the Hennepin County Probation Office. Petschon had previously entered a plea of guilty on December 7, 1959 to an information charging him with the basic science violation.

Petschon had originally been charged with the crime of abortion in a complaint signed by a representative of the Minnesota State Board of Medical Examiners on November 6, 1959. However, the authorities later decided that the facts and circumstances surrounding the case justified reducing the charge from a felony to a gross misdemeanor. A written statement signed on October 23, 1959 by a seventeen-year-old, married Edina woman indicated that although two attempts were made to perform an abortion upon her in July, 1959, she did not abort and, at the time the statement was given, she was approximately seven months pregnant. The evidence also indicated that all of the arrangements for the abortion, including the payment of $300 to Petschon, had been made by her mother and by her husband's parents and grandparents. The abortion complaint was therefore dismissed and a charge of violating the basic science law was filed against the defendant.

Upon being questioned by Judge Hall prior to being sentenced, Petschon stated his occupation is that of a painter. Although the defendant admitted that he had been paid $300 in this case, he claimed that he did not "really try" to perform the abortion but that he "just needed the money." Petschon has no training in medicine and is not licensed to practice any form of healing in Minnesota. The defendant denied that he had previously been convicted of a criminal offense and a search of the records failed to disclose that he has a prior conviction.

TOTAL AVERAGE COSTS FOR FOUR YEARS OF MEDICAL SCHOOL AND STUDENT INDEBTEDNESS

The total average expenses, according to family composition for four years in medical school were tabulated for 4,277 men members of the graduating class of 1959. Assuming that expenses were evenly distributed for each of the four years, the total cost per year would be: $2,376 for a single student; $2,763 for a married student; $3,210 for a married student with one child; and $3,925 per year for a married student having two or more children.

A sample study of medical student financial considerations in 1953 by Counts & Stalnaker indicated that about one-third of the medical students expected to be in debt at graduation and 3 per cent expected to be in debt more than $10,000. The preliminary figures for the 1959 graduating class show 52 per cent actually in debt, and 6.5 per cent in debt more than $10,000.—Association of American Medical Colleges.

Medical Legal Opinion

● *The purpose of this section entitled Medical Legal Opinion is to publish news of recent litigation concerning medical practice as well as to cite past actions and opinions of the Court in medical legal matters as a means of refreshing our knowledge of such procedures.*

Code for Interprofessional Relations

Minnesota State Bar Association

Minnesota State Medical Association

The following Code has been drafted by the joint efforts of the Medical Advisory Committee of the Minnesota State Medical Association and the Interprofessional Code Committee of the Minnesota State Bar Association. It should be a helpful guide and standard for professional conduct in both professions. Medical legal problems whether desired or not, have become a part of our job. The Code is informative and worthy of your study. It is to be considered for official adoption by both the Minnesota Medical and Bar Associations at the 1960 Spring Meetings.

HARVEY NELSON, M.D.
Chairman, Medical Advisory Committee

PREAMBLE

Acknowledging that a substantial part of the practice of law and medicine is concerned with the problems of persons who are in need of the combined services of an attorney at law (hereinafter called lawyer) and a doctor of medicine (hereinafter called physician), and that the public interest and individual problems in these circumstances are best served by the co-operative efforts of all concerned, we, the members of the Minnesota State Bar Association and the Minnesota State Medical Association, do hereby adopt the following interprofessional code as the standard for proper, ethical conduct for lawyers and physicians.

INTERPROFESSIONAL RELATIONS

Physicians and lawyers, as members of learned professions, have much in common. The state licenses the members of each profession to administer to the needs of and to carry out social responsibility to the public. Each is dedicated to the principle of free choice—freedom of choice in the selection of a physician to safeguard the health of the individual, and freedom of choice in the selection of a lawyer to safeguard an individual's freedoms and rights as a citizen. Each is bound by a code of ethics dedicated to the most worthy objectives inherent in the trust placed in each profession by the community.

The physician has responsibility for the care of his patient, not only in health but also in disease and injury. He is the adviser and confidant of his patient in matters of health. He must administer to the needs of his patient to the best of his ability and in accordance with the high precepts of the Hippocratic Oath.

The lawyer represents his client as advocate in legal proceedings and as counsellor in business and personal affairs. He is the adviser and confidant of his client in legal matters. He performs his duties as an officer of the court, sworn to support and defend the Constitution of the United States and of the state or states in which he is admitted to practice with high standards of conscience and morality.

The members of each profession are pledged to maintain the confidence and to preserve inviolate and secrets of their patients or clients, as the case may be.

Each profession is obligated by its own stature to respect and honor the calling of the other. Neither the fact nor the appearance of incompetence, corruption dishonesty or unethical conduct on the part of individual members of either profession can be tolerated. It, therefore, follows that each profession must vigorously support within its own ranks, as well as within the ranks of the other, those ethical concepts which each has found necessary in the public good. But when doing so, the

Action is to be taken on this code by the two organizations this spring.

members of each profession must keep in mind that the members of the other profession have been found competent to be such by appropriate authority, that there are differences in the capacities and characteristics of the practitioners of the other profession, and that while law and medicine may each be termed a science, each is an inexact science and such inexactness is and always will be accented by the human limitations of its practitioners.

This interprofessional code constitutes recognition that with the great development in the science and art of both medicine and law, physicians and lawyers are drawn into more and more associations, as the law calls with increasing frequency upon medicine for its scientific knowledge and its evaluation of facts so that the rights of individuals may be appropriately determined before various tribunals.

I. Medico-Legal Aspects Before Trial

The physician becomes involved in the legal process either because he has been engaged for the purpose of diagnosis, care or treatment of some patient whose legal rights are being litigated or because he has been engaged for the purpose of litigation rather than for diagnosis, care or treatment. If he is a physician engaged for the purpose of diagnosis, care or treatment, he will be referred to herein as the attending physician, whether he was the physician who treated the patient during the entire course of his illness or injury or the physician called as a specialist with respect to certain aspects of diagnosis, care or treatment of the patient. If he is a physician engaged for the purpose of litigation, he will be referred to herein as the examining physician.

A. *Professional Obligation of Physician to Patient in Regards to Litigation.*—The attending physician has a duty to assist his patient with respect to any litigation involving the conditions which the physician has treated. This duty arises from his general obligation to assist in the administration of justice and his specific responsibility for the welfare of his patient.

Administration of justice is essential to orderly society. An effective system for settlement of claims involving the physical or mental condition of a person is essential to judicial administration. Disposition of such claims either by trial or in anticipation of trial must be based on facts relating to (1) liability and (2) damages. The attending physician, by virtue of the confidence reposed in him by his patient has unique knowledge of the physical and mental condition of his patient; the care and treatment required; and the degree of permanent loss, if any, to be anticipated. The issue of damages cannot be fairly resolved without these facts.

It is for the physician to determine the actuality or probability of facts pertaining to his patient's condition. It is for the lawyer to determine when, how and under what circumstances such facts are most appropriately to be presented.

B. *Medical Conduct Before Trial.*—The information obtained by the attending physician in the course of his examination and treatment of a patient and any written report thereof are legally privileged, except that in situations involving the Workmen's Compensation Act an attending physician designated by the Commission or whose services are paid for by the employer may be required to testify as to any information acquired by him in the course of treatment or examination. The information obtained by an examining physician and any written report thereof are not privileged. Nevertheless, an examining physician should not reveal such information or the contents of such report to anyone other than the person employing him without first obtaining the written consent of such person.

Neither the attending physician nor the examining physician should express any opinion to the patient as to the settlement value of any claim for personal injury.

The examining physician, acting for a party adverse to the person he is examining, should, where taking a medical history, attempt to elicit only such facts as are pertinent to his examination; he should not attempt to obtain statements which might constitute admissions with reference to any accident out of which the litigation arises. Such an examining physician should not solicit the findings or the opinions of or consult with the attending physician, nor should he suggest to the person being examined any treatment, comment to such person on any treatment already received, or divulge to such person any of his medical findings or opinions.

It is not desirable for a lawyer to be present when his client is being examined by an examining physician whether the physician is employed on behalf of his client or on behalf of an adverse party, but there is no reason why the lawyer should not discuss with such physician, either before or after the examination, any aspect of the examination that may be pertinent.

C. *Legal Conduct Before Trial.*—A frank discussion of the issues and opinions between the physician on the one hand and the lawyer on the other hand prior to trial is to be encouraged. The lawyer may properly point out the legal foundation for medical evidence and the reasons for it. This does not, however, mean that the physician's testimony must be in accord with these views, for a lawyer by his conscience and his ethics is prohibited from attempting to color or distort the professional opinion of a physician to be called as a medical witness in the trial of a case. Both the lawyer and

the physician must share the responsibility for improperly presented or fraudulent medical testimony. Such testimony is unworthy of both professions.

D. *Medical Reports.*—The physician should always stand ready to furnish written reports to lawyers. This statement applies not only to examining physicians but also to attending physicians. The lawyer when requesting a written report from a physician concerning the condition of a patient should make his request in writing and should direct the physician's attention to the particular condition which interests the lawyer.

The lawyer should not expect an attending physician to furnish a report unless the physician has first received a written authorization from the patient permitting the physician to furnish such a report, or the lawyer's letter to the physician contains a signed acknowledgment by the patient of the lawyer's authority to act in his behalf.

A request for a written report should ask for history, diagnosis, treatment, prognosis and medical fees up to the date of the report.

The physician has an obligation to keep adequate records which may be used to supply to a patient's lawyer all information regarding the patient-client's medical history, and to retain control of x-rays.

Requests for medical reports should be honored promptly, as undue delays in providing medical reports or bills bearing on a patient's legal rights may prejudice the patient's rights.

If a physician is unable to state a complete medical evaluation and prognosis at the time it is required, he should so notify the lawyer and suggest to him that he request a further medical report at a later time. In such instance a preliminary report and medical bill, clearly designated as such, will often serve the patient's needs adequately.

E. *The Interprofessional Conference.*—Personal conferences between the lawyer and each physician, whether he be an attending physician or an examining physician, are always proper and generally should be regarded as professionally obligatory.

Conferences should be scheduled at mutually agreeable times and under circumstances so that they may proceed without interruption.

Several conferences may be necessary. An initial conference long prior to trial and in some cases even prior to the commencement of a lawsuit is often desired by the lawyer so that he may be early apprised of the medical aspects of the claim, knowledge of which is, of course, essential to an evaluation of the claim. Interim conferences to discuss the patient's medical progress are often also necessary. If the physician is to be a witness, a final conference should be held as shortly as possible before the physician is to give his testimony. At this conference the lawyer should explain the legal aspects of the case and the facts he expects to develop; and fully and with complete candor the physician should explain the medical aspects of the case. If a hypothetical question is to be asked, the lawyer should clearly outline it at the conference. The physician should review with the lawyer at the conference all his notes, records, memoranda and x-rays even though he does not intend to use them in his direct examination because they may be used in cross-examination. Before the conference concludes the physician should volunteer any pertinent medical fact not previously discussed.

F. *Arrangements for Medical Testimony in Court.*—The lawyer should make arrangements with the physician who is to be a witness for the physician's appearance at a particular time and place and for the physician's testimony to be given as close to the specified time as possible. It is the obligation of the physician to be present at the specified time. The lawyer should give the physician as much advance notice of the specified time as is reasonably possible, but the physician must realize that the lawyer cannot control the court calendar and that unanticipated dispositions of preceding cases frequently prevent the lawyer from giving as much advance notice as might be desired. When a case is settled, the lawyer should promptly notify all physicians involved. Prompt notice is particularly important when a case is settled after a time for the physician's appearance in court has been set.

G. *Subpoenas to Secure Medical Testimony.*—The lawyer should make every effort to arrange his client's medical evidence without the use of subpoena. In the event medical evidence cannot be obtained by arrangement, the lawyer may subpoena the physician. The physician must appear at the time requested and should not take offense at being subpoenaed. In the event a lawyer finds it necessary to subpoena a physician, the lawyer should notify the physician in ample time, preferably in advance of service of the subpoena, of his intention and insert in the subpoena a time for appearance as nearly as possible acceptable to the physician. A lawyer who subpoenas a physician should not expect the physician to bring with him his notes, records, memoranda and x-rays unless the physician has been served with a subpoena duces tecum.

Even though all physicians are experts in the eyes of the law, a physician can be compelled by subpoena to appear and testify upon tender to him of the statutory witness fees payable to any lay person who is subpoenaed. If a physician who appears in answer to a subpoena is examined with respect to any subject upon which he is an expert, the judge may at the conclusion of his testimony allow him a reasonable expert witness fee.

II. The Medical Witness at Trial

A. *Appearance of Medical Witness.*—The proper, fair and impartial presentation of medical testimony is the joint responsibility of the physician acting as a medical witness and both examining lawyers.

The persons who are to hear and interpret the medical testimony, be it a jury, judge, or other presiding official, must necessarily observe and consider the appearance of the witness and presentation of the testimony. A medical witness should maintain a professional attitude in his appearance and should present his testimony in language that a layman can understand.

Our system of justice assumes that medical witnesses as well as other witnesses are impartial as to the facts within their knowledge. They are not and should not be advocates. A dogmatic, uncompromising, and argumentative attitude assumed by a witness instead of a firm but professional attitude based on honest convictions established on scientific principles will work to the detriment of the witness and as a result will work to the detriment of the patient on whose behalf he is testifying.

A lawyer should not engage in the abuse of any witness, including a physician, whether the witness be called by one side or the other. The established rules of evidence give ample opportunity for testing the competence and credibility of all witnesses, including a physician, making abusive examination on the part of a lawyer unnecessary and unjustifiable.

The physician should realize that it is the privilege and obligation of the lawyer for the opposing side to conduct his cross-examination with a vigor in an effort to explore the foundations of medical opinion and to expose weakness which may appear in either the basis or content of such opinions. The physician should not be upset or assume an antagonistic attitude toward such cross-examination, providing the examining lawyer conducts it in a professional and gentlemanly manner. The physician must realize that such cross-examination is most probably based upon contrary medical interpretation of the objective facts known to all. A refusal to tolerate or to recognize a contrary view will not be in the best interests of the administration of justice.

B. *Medical Testimony.*—A physician should bring with him to court all his records with repect to the patient about whom he is testifiyng and may request that the hospital records with respect to such patient also be present in court. A lawyer should not counsel against the production of such records. When preparing to testify or when testifying a physician may examine such records to refresh his recollection. Once he has used them for such purpose, the lawyer for the opposing party may examine them too.

The qualification of a medical witness involves an inquiry into his medical education, post graduate training and research and his membership in various medical organizations. The physician should be prepared to give a résumé of these professional qualifications without hesitation but without undue elaboration.

In the giving of testimony, the physician under no circumstances should permit any bias, prejudice, favoritism or personal interest to influence or affect his testimony. If the physician is asked a question to which he does not know the answer, he should so state and make no attempt to speculate or guess or theorize or give answers not responsive to the question propounded. A physician should not hesitate to express his opinions which are based upon a reasonable medical certainty. The medical witness is not required to exclude all doubts from his mind but may render his testimony as an opinion couched in expressions which fall short of an absolute conviction of accuracy. Simply because someone else might not agree with his opinions should not cause the physician to hesitate in expressing them. He must also remember that it is only fair that a contrary interpretation of the medical facts may exist and may be admitted. The physician must state his opinion if he has one. However, if he feels he is not qualified to give one, he should so state, and if he has no opinion he cannot be compelled to give one.

Trials are conducted according to rules of evidence and a physician may find that frequently during the presenting of his testimony there will be objections. These objections by the lawyers are merely a request to the court to pass upon the materiality, the relevancy, or the competence of the testimony being offered. The court will rule according to the rules of evidence and the decision will be made as to whether the testimony should be considered along with other evidence in the case. The physician should not feel frustrated by these frequent interruptions since they are important and essential to protect the relative rights of the clients who are litigants.

It is frequently necessary to use hypothetical questions in illiciting testimony from medical witnesses. Such questions can be lengthy, troublesome and confusing if not properly prepared and presented. It is the lawyer's obligation to present such questions so as to be free from ambiguities and to eliminate any possible misunderstandings. The medical witness in attempting to answer the question, must, of course, be sure that he understands all of its elements and that they are sufficient and complete enough so that he can properly predicate his opinion thereon.

C. *Ethical Limits of Medical Testimony.*—It is a rare occasion when intentional false or improper medical testimony is given in the trial of a case. However, it has occurred. Similarly, there are occasions when lawyers exceed the limits of pro-

priety and attempt to introduce improper medical testimony or attempt to influence the testimony of the medical witness.

Each of the members of both professions has a duty to satisfy himself as a matter of conscience and professional judgment that the person doing so has exceeded the limits of ethical medical testimony or ethical handling of medical witnesses and once doing so has the obligation of reporting such activity to the appropriate organization within the profession which is set up to handle such matters.

The reputation of a professional person is his most precious and valuable asset. Therefore, the reporting of such improprieties against a member of one's own profession or against the member of another profession is a matter of great seriousness and calls for a high degree of discretion. It must be remembered that in an area such as medical testimony, there is a large degree of variance in opinions and in most cases these opinions are based upon sound medical authority. The possibility of unintentional misstatements or representations also must be considered. Therefore, before any action is taken of any kind, the person doing so must be absolutely certain in his own mind and conscience that such action is warranted.

Conversely, it is just as serious to abstain from reporting such misconduct as it is to make a groundless charge. Therefore, when a member of either profession becomes convinced that such misconduct has occurred, it is his duty to report it.

III. Compensation of Medical Expert

A. *Medical Fees*

1. *Contingent Fees.*—It is improper for the lawyer and the physician, whether he be an attending physician or an examining physician, to enter into any arrangement making the payment of medical fees, or the amount thereof, contingent upon the outcome of the litigation. Fixed fees should be established prior to the examination or court appearance.

2. *Attending Physician.*—The expense of care and treatment of the patient is the obligation of the patient, irrespective of the litigation or the outcome thereof. The expense, if any, for preparation of medical reports for use by the patient's lawyer is the obligation of the patient. The expense of court appearance or preparation therefor is the obligation of the patient. The lawyer for the patient is under no legal obligation to pay such fees.

It is improper for the attending physician to insist, as a condition precedent to his testimony, that the lawyer for the patient guarantee payment of an unpaid bill for medical services, or bills for services to be incurred for the court appearance.

3. *Examining Physician.*—The expense of an examination and report by an examining physician, as well as x-ray expense and similar costs necessary for a complete examination, are obligations in the first instance of the lawyer requesting the same. Similarly, the expense of court appearance is an obligation in the first instance of the lawyer requesting the same. This fact does not relieve the client of his ultimate liability to pay the examining physician or reimburse his lawyer.

It is proper and desirable practice that whenever a lawyer refers a client to a physician for examination he should do so in writing, stating the terms of the reference. If the lawyer disclaims liability for the fee or if the physician doubts the lawyer's credit, the physician may be justified in withholding his report until the fee is paid or in declining to testify until mutually satisfactory financial arrangements have been made.

Payment of the examining physician's fees should be made promptly upon completion of his services. Delay in the final disposition, such as appellate procedure, is not sufficient reason for a lawyer to delay payment.

4. *Court Appearances.*—The lawyer and his client should realize that a physician's fee for a court appearance is based upon many factors among which are not only actual time away from office but also stand-by time—i.e., the hours for which the physician has not been able to arrange a normal schedule of appointments either because he does not know exactly when he must appear in court or because he does not know exactly when he will return from court. They should also recognize that a physician is entitled to charge a fee for a court appearance if a case is settled while he is in the courtroom or if he has incurred stand-by time even though in either case he has not testified.

B. *Professional Obligation of Attorney to Protect Physician for Fees on Services Rendered.*—

In the event of recovery, the lawyer has an obligation to use all reasonable measures to assure payment by the client of the statement for services of the attending physicians, not only for the court appearance but also for services rendered. Whenever possible, unpaid statements should be satisfied as part of the process of distributing funds recovered in the litigation. A lawyer unable to make arrangements for satisfaction of unpaid medical bills should promptly notify the physician of such facts.

INTERPROFESSIONAL UNDERSTANDING

This code of interprofessional relations has been designed to promote better understanding between physicians and lawyers. If it is studied carefully and followed diligently by members of both professions, it should go far to eliminate the frictions that have arisen and to enhance the areas of understanding. Improvement of the relationships between the two professions will enable the two professions to progress together in their service to humanity and its individual ills, whether of body, of mind, or to rights guaranteed under our system of justice.

History of Medicine in Minnesota

PIONEER PHYSICIANS OF STEVENS COUNTY, MINNESOTA

JOSEPHINE EDDY, GRACE HALL,
A. I. ARNESON, M.D.
Morris, Minnesota

ROBERT ROSENTHAL, M.D.
Saint Paul, Minnesota

(Continued from January 1960 issue)

Dr. William M. Ray started to practice medicine in Morris in January, 1879, opening his office at the Perkins House. His professional card appeared in the Morris newspaper from February, 1879, to October, 1881. It seems he alternated between Morris, Stevens County, and Benson, Swift County; at least, in March and April of 1879 he seemed to be staying in Benson and came to Morris only when needed. In October, 1880, the local paper states that he planned to locate permanently in Morris.

A news item of November 10, 1881, tells that Dr. Ray had left for Cokato, Wright County. He is, no doubt, identical with the Dr. Ray who practiced in Delano from 1883 through 1887.**

Dr. Ray graduated from the Missouri Medical College, St. Louis, Missouri, in 1868 and came in that year to Chaska, Scott County.† He left there after five months and went to St. Paul, which he left after a very short stay, late in 1868, to go to Glasgow, Missouri. It is not known whether he stayed there until his appearance in Stevens County in 1879.

It is also not certain, but probable, that he is the same Dr. William Ray who practiced in Otter Tail County in the 1880's; if so he must have moved there very late in that decade and practiced several years at Pelican Rapids and later in Fergus Falls, leaving Fergus Falls in 1904 for Phillipburg, Montana.

He seems to have been an active practitioner who left his mark in Wright County where he was a charter member of the Crow River Valley Medical Society in 1883 and was one of the authors and signers of the the signers of the articles and by-laws of this first medical society of Wright County. He was licensed in Minnesota on December 21, 1883.

It is difficult to understand why he was such a rolling stone, although he has been described as a jovial personality. He was at least four years in Delano, Wright County, and was not too successful in establishing a satisfactory practice there.

Dr. Stephen (Steve) H. Spurr "has decided to cast his lot with the people of Stevens County and has opened his office in the Spooner Block" states the *Mor-*

**Unpublished medical history of Wright County.

†"History of Medicine in Scott and Carver Counties," MINNESOTA MEDICINE, 31:798 (July) 1948.

ris Tribune of May 6, 1896. After three years in Morris,‡ he got into trouble with the law for an alleged abortion. A warrant was sworn out by Dr. E. W. Young for his arrest and that of another man on the charge of performing the abortion and trying to buy off the complaining witness with money and even an offer of marriage. There was action to have Dr. Spurr's license revoked. The doctor, whose father, N. R. Spurr, had been county auditor of Stevens County for many years, was cleared by the grand jury although the case was played up in the newspapers.

Immediately after this incident, he left Morris and went to St. Paul, where he studied dentistry. He did not practice medicine there but was called before the grand jury several times because of "immoral practices," without ever being indicted.

Dr. Spurr was a graduate of the College of Homeopathic Medicine and Surgery at the University of Minnesota in 1893 and was licensed on April 7 of the same year. Before coming to Morris in 1896, he practiced in Michigan and in Herman (Grant County), Appleton (Swift County) and Granite Falls (Yellow Medicine County), Minnesota§, though it seems that he had located for a while in Morris before he moved to Appleton around the first of November, 1895.

Dr. Spurr was born in Maine on October 10, 1871. He died suddenly, in the Globe Building in St. Paul on April 27, 1928, due to chronic myocarditis*, at the age of fifty-six and was buried in Forest Cemetery in St. Paul. He was survived by his wife, Edna. Dr. Spurr had lived in St. Paul for twenty-eight years.

Dr. Douglas R. Sutherland was born at Poughkeepsie, Dutchess County, New York, on Nov. 9, 1852, the son of Walter and Julia Sutherland.

Dr. Sutherland received his primary education in the state of New York and in 1869 matriculated at Yale College. He studied at Yale for two years, but, because of failing health, was compelled to discontinue his studies there. For a year he studied medicine at home, then entered Columbia College of Physicians and Surgeons from which he was graduated in 1874.

In December, 1873, he married Pauline Doty. Three children were born to this union, Essie, Mae and Douglas.

He opened an office in Poughkeepsie, New York, and continued to practice there for five years, with the exception of one year spent in the South for his health. In 1879 he came to Stevens County where he resided until the time of his death.

In appearance Dr. Sutherland was of medium size and, when he first came to Stevens County he wore "mutton-chop" whiskers. Later he was smooth-shaven. His manner was somewhat distant, especially among strangers. He made his calls to his patients and his trips around his farm on horseback at first, later using a top-buggy and horses.

When Dr. Sutherland came to Stevens County, he located on a three thousand acre farm lying in the townships of Morris and Darnen and commenced farming on an extensive scale, cultivating one thousand and ten acres. He remained on the farm some five years and then traded it for Minneapolis property.

---

‡*Morris Tribune,* July 22, 1899.

§His stay in Granite Falls could not be verified, and the excellent "Medical History of the County of Yellow Medicine" by Mildred B. Lee, MINNESOTA MEDICINE, June, 1953-May, 1954, does not mention him.

*There was a rumor that he committed suicide. This probably originated because the coroner, Dr. Ingerson, was called in on this case of sudden death.

He then moved to the village of Morris and for two years was connected with the First National Bank as vice president and president, after which he sold out his interest in the banking business and became occupied in the practice of his profession. In the files of the present Arneson Drug Store prescription No. 2 was signed by Dr. D. R. Sutherland.

In 1880, Dr. Sutherland erected an elevator at Morris and operated it under the firm name of D. R. Sutherland and Co. for three or four years. In 1881 the same firm put up an elevator at Donnelly, which they operated until its destruction by fire in 1883. Also, in 1880, he laid out the Sutherland Addition in the village of Morris and built a beautiful home there.

Dr. Sutherland was one of the most public-spirited, prominent and influential citizens in this part of the state. He was a member of Golden Sheaf Lodge, No. 132 A.F. and A.M., Mt. Lebanon Chapter No. 47, R.A.M.; Bethel Commandery No. 19, Knights Templar, Minneapolis Consistory, No. 2; and Zuhrah Temple of Minneapolis. He was Eminent Commander of the Commandery, and was one of the officers of the Grand Commandery of the state. He was also a member of the Odd Fellows fraternity and of the Encampment.

Dr. Sutherland was active in many community affairs. An item in the local paper June 26, 1884, states: "In Fourth of July program Dr. D. R. Sutherland is listed as Marshall of the Day. For such occasions he dressed in his Masonic uniform with black hat, a long white feather going from front to back; a long coat decorated with gold cord and white lace trimmings. He rode horseback and made a very imposing figure." He was president of the local school board for several years, a warden in the Episcopal Church, a commissioner on bridges on Toqua Road, president of the Stevens County Agricultural Society and president of the Board of Trade in 1882. He was Stevens County coroner (elected on the Republican ticket), director of the library and reading room, and was county health officer for many years.

Dr. Sutherland enjoyed hunting and was president of the Sportsman's Club in Morris.

No man in the county was more widely or more favorably known. His extensive property interests and his active business life, together with his energy, enterprise and business ability, have connected his name indissolubly with the history of the growth and development of this part of the state.

Dr. Sutherland's obituary appeared in the *Morris Tribune*, April 29, 1896.

"Eminent Physician Gone.—Dr. D. R. Sutherland died on Arbor Day after just one week's sickness of pneumonia. The angel of death descended once more in our midst and picked out one of our noblest men; a man who had administered to the cares of the sick and needy for the past twenty-two years; a man who was beloved by all who knew him, and a man whose ambitious desires carried him to the top of fame in his profession, being acknowledged one of the best physicians and surgeons in the state of Minnesota. He contracted pneumonia while visiting patients through that awful damp and chilly weather a couple of weeks ago and was taken to his bed on the 17th. Everything that skill and science could do was done, but without avail. He gradually sank from the beginning, until the 24th when he breathed his last in this world of care and trouble surrounded by a heart broken family. Dr. Wheaton of St. Paul, Dr. Jones of Minneapolis, Dr. Hand of Litchfield were constantly by his side during the last of his sickness, and were doing all that human hands could do. His remains were taken to Litchfield for interment."

On the same date the following item appeared in the paper: "Mrs. D. R. Sutherland, her daughter, Mae, and son, Douglas, left today for Litchfield where they will make their future home. The loss of Mrs. Sutherland and Mae will be keenly felt by Morris society, as they were prominent among the leaders." Later Mrs. Sutherland and children moved to Kansas City, Missouri.

A Dr. Thomas and his wife, who was also a physician, came to Chokio shortly after the turn of the century. They had a daughter, Jennie. This is all the information available about them.**

Dr. F. C. Trumpour was born May 5, 1870, in Prince Edwards County, Ontario, Canada. He received his education in Canada. In 1891 he was graduated from the Medical Department of Toronto University where he took a three years' course in classics and science and a five year medical course. Besides this, he took a special course in surgery and secured the degree of Master of Surgery as well as that of M.D. He also graduated from the College of Pharmacy. He was constantly abreast with the advancement of new ideas in medicine and surgery. He possessed a multiple nebular vaporizer which, in 1898, was new for treatment of lung, throat and nose.

After graduation, Dr. Trumpour went into partnership with Dr. B. W. Randall in hospital service in Toronto. He then located in Elgin, Iowa, where he remained two years. From there he went to Graceville, Big Stone County, where he spent three years.†

Dr. Trumpour came to Morris, June 8, 1897, from Graceville, and opened offices formerly occupied by Dr. Sutherland. In June, 1898, he moved his office to rooms over Larson's drugstore.

In appearance Dr. Trumpour was of medium height and build and had a dark complexion.

In July, 1897, Dr. Trumpour was appointed regular physician for the government school. There were forty-five Indian children there at the time, eight of whom had the measles.

In December of the same year, Dr. Trumpour caught a cold which developed into pneumonia. This proved fatal and he passed away at his home Dec. 18, 1898. The following obituary appeared in the local paper Dec. 24, 1898:

"Sad Harvest of Death. Dr. Trumpour Passes Away.—The death of Dr. F. C. Trumpour came as a severe shock to the people of Morris last Saturday. All knew that the doctor had been suffering from an attack of inflammatory rheumatism and that he had also contracted pneumonia, but word had gone out that the doctor had safely passed the crisis of the disease, so that the sudden announcement of his death came with double force. Dr. Trumpour had been in Morris only a year and a half, yet in that time he had so endeared himself to a large circle of friends by his self-sacrifice in the practice of his profession that his death will be lamented by his friends as the loss of an own relative might be.

The abundant sympathy which is now being expressed for Mrs. Trumpour is but an estimation in which the doctor and his bereaved wife are held by the people of Morris—the former from the fact that every patient he ever had felt that in him they had a friend whose sole aim in his profession appeared to be the care of his patients, the latter for those qualities of womanly virture which made her a queen in her home—a faithful wife and an endearing friend."

Dr. F. C. Trumpour and Gertrude Tennant were married on June 2, 1892, at Brockville, Canada. She and their three children, Mildred Lucille, Traverse Tennant, and Helen Gertrude, survived him and apparently returned to Canada with her parents.

**Communication of Mrs. Oden L. Henry. (March 6, 1956)

†It is said that the partnership with Dr. Randall was dissolved in 1895, but this probably is incorrect. If he really practiced five years in these two towns, he must have left Toronto in 1892.

Dr. E. R. Wait‡ was the first physician in Stevens County of whom a definite record could be found. The *Frontier Business* of August 11, 1876, printed his professional card, "Dr. E. R. Wait, physician and surgeon, Refers. by permission to Drs. Murphy, Wharton and Hand of St. Paul. Office at Central House, Morris, Minn." Dr. Wait must have come to Morris earlier than the date of the card indicates, because, when he left the county in the same month (the newspaper stated on August 18, 1876, that he was gone), he had been well established and was very popular. He was long remembered for his use of sulphur and molasses in spring and some concoction which he used as a cure-all and which he advertised to a considerable extent. His place in Morris was taken by Dr. W. E. Holden in the spring of 1877.

Although nothing is known of his medical background, it seems he must have had a pretty good training as his association or acquaintance with Drs. Murphy, Wharton and Hand, three of St. Paul's outstanding physicians of that period indicates§. Another indication is the fact that he was elected to membership in the Ramsey County Medical Society in May, 1874, and only a month later was made secretary and re-elected to this position in October of that year; he also became a member of the executive committee.

Dr. Wait left St. Paul late in 1874 or early 1875. He may have then moved to Morris. When he left Morris, he was a very sick man with affected lungs resulting in hemorrhages; he returned to St. Paul and there was justified fear that he would not come back to Morris.

Dr. E. W. Young came to Morris in December of 1898 from Barrett, Grant Co., Minn.

In appearance, at that time, the doctor was stockily built, and of fair complexion. He was of middle age when coming to Morris, although comparatively young in the general practice of medicine.

Dr. Young was graduated with a bachelor of arts degree from Carleton College in 1879 and immediately went into school work. For many years he taught with success, but meanwhile read medicine. He was graduated from the Medical Department, Hamline University, in 1896, and was licensed on April 14 of the same year. After his medical education was completed, he was for many years a member of the faculty of College of Physicians and Surgeons in Minneapolis.

The following item was published in the *Barrett Lake Breeze* on Jan. 7, 1899:

"Complimentary to Dr. Young.—Dr. Young departed Tuesday for Morris where he has decided to locate—as we stated in last week's *Breeze*, Barrett can ill afford to part with the doctor, and his loss will be felt by all. During his residence of but one short year in this village, Dr. Young has made a host of friends, and it is to be regretted that the practice he has acquired did not warrant his remaining. He has identified himself with every commendable understanding in the village, was a conspicious factor in all religious and social affairs, and the *Breeze* unhesitatingly commends to the people of Morris and vicinity a gentleman of true merit and a physician of much ability. Mrs. Young and children will remain here until a suitable place of abode can be obtained in Morris."

Dr. Young practiced in Stevens County only until January, 1900, when he was appointed surgeon for the Minneapolis Iron Works, which employed hundreds of men.

---

‡His first name apparently was Edson.

§It is known that he studied in the office of Dr. John Henry Murphy.

In the January 6, 1900 issue of the *Morris Tribune,* Dr. Young's departure was noted with regret as the doctor and his family had made many friends. It was Dr. Young who swore out the warrant for the arrest of Dr. S. H. Spurr, accused of performing an abortion. According to the newspaper story (July 22, 1899), "Dr. Young was offered a certain amount of pecuniary remuneration in case the prosecution was not pushed. This offer was made before the warrant was sworn out. Dr. Young, of course, would not enrich himself by any such criminal means." There is reason to believe that Dr. Young's practice was not too successful in Morris; one of the indications is the fact that he tried to broaden his area of practice by making arrangements in October, 1899, for regular visits in Cyrus, Pope County.

ADEQUATE MEDICAL CARE GREATLY REDUCES HAZARDS OF SERIOUS SURGERY IN AGED

Older people today can "withstand serious surgery almost as well as the young" provided pre-operative preparation is adequate, according to Dr. Edward E. Jemerin of the Mount Sinai Hospital, New York, in an article in the March, 1960, issue of the *Journal of the American Geriatrics Society.*

Noting that the need for surgery in the aged has paralleled the increase in our aging population, he asserts that "the contraindications of a few years ago are being neutralized to such a degree that it is now rarely necessary to withhold indicated surgery in the aged."

He stresses, however, that emergency surgery in the aged should, wherever possible, be avoided because careful pre-operative preparation is vitally important. Some of the important pre-operative steps listed by Dr. Jemerin include the following:

The patient should be admitted well in advance of the operation;

He should be given a complete physical examination and imbalances or disease states such as diabetes or heart failure should be treated;

If the patient is debilitated, testosterone is "often beneficial," and adrenal steroids may improve operability in conditions "which may have taken their toll of the adrenal capacity to respond;"

Existing infection should be "treated vigorously because of the patient's low resistance."

As far as emergencies are concerned, multiple-stage procedures are sometimes advisable, in order to convert emergencies into elective procedures "with their appreciably lower mortality," Dr. Jemerin says. Too, prophylactic surgery may prevent emergencies.

Dr. Jemerin also stresses the importance of post-operative care to avoid complications.

The incidence of such complications is high, he adds, with pulmonary ones ranking as the most frequent. Causes of death in order of frequency are cardiac, pneumonic, infectious, embolic and renal.

Adequate post-operative care, Dr. Jemerin says, includes making sure that the patient obtains adequate pulmonary ventilation by getting him to move frequently in his bed; getting him on his feet as soon as possible; instituting early active and passive exercises to prevent blood clots; and using hormones and antibiotics as indicated.

Minnesota Blue Shield

Minnesota Blue Shield has purchased a three-story building at 2218 University Avenue, St. Paul, which will be the organization's new home, following alterations and remodeling of the interior and exterior.

The three floors plus basement will provide an area of approximately 24,000-square feet.

The purchase was approved at a meeting of the Blue Shield Board of Directors, February 26, 1960.

Since 1951, Blue Shield has maintained headquarters in the Blue Cross building at 2610 University Avenue, St. Paul.

IBM high-speed data-processing equipment has been leased by Blue Shield and will be installed at the new location to handle all accounting, billing, and record-keeping operations. James Shobe, St. Paul, formerly on the staff of International Tabulating Company, has been appointed head of Blue Shield's data processing division.

Dr. C. A. McKinlay, president of Minnesota Medical Service, Inc., said, "The new headquarters will give Blue Shield a less expensive yet completely adequate home. It will house complete facilities for claims processing, accounting and billing and will be sales headquarters for the Blue Shield division of Enrollment and Service, operating through its appointed representatives in the field."

In addition, a regional office of the Division of Enrollment and service has been established at 501 Providence Building, Duluth, Minnesota.

* * *

During 1959, Minnesota Blue Shield paid a total of $10,197,592.98, or nearly $850,000 a month, in surgical-medical service expenses for its subscribers, setting a new record and raising the total payments since the plan began in 1947 to nearly $61,000,000.

The 1959 payments were about 5.3 per cent greater than the 1958 figure of $9,686,819.04.

The number of services paid for also rose to a new high of 395,696, compared with 365,654 in 1958.

Principal categories of services paid for 1959 included: 23,237 obstetrical care; 70,749 skin surgery, other than suture of wounds; 16,326 suture of wounds; 26,285 surgical care of bones, joints, and tendons; 10,217 endoscopic procedures; 3,508 neuro-surgery; 3,735 proctology; and 8,664 tonsillectomies.

On December 31, 1959, there were 333,779 Blue Shield contracts in force, covering 865,833 participants. These included 290,194 contracts under Plan "A" with 758,878 participants; 42,254 contracts under Plan "B" with 105,624 participants; and 1,331 Senior Citizens contracts.

The new diagnostic x-ray and laboratory coverage, which is being added to all contracts on their anniversary dates, was, by the end of 1959, extended to 292,572 persons under Plans "A" and "B".

Included in operating expenses were service charges paid to Blue Cross of $983,449.45.

The record total of $10,197,592.98 paid out by Blue Shield for surgical-medical services expenses represented 86.6 per cent of the year's receipts of subscriber's payments. From the balance, the sum of $217,363.04 was transferred to Blue Shield's reserve for future medical, maternity and surgical care and contingencies, and $200,000 was set aside to meet unreported cases. This addition makes the present total set aside for unreported cases of $1,650,000.

* * *

The Minnesota Radiological Society at its winter meeting in St. Paul, March 5, unanimously adopted a resolution commending Minnesota Blue Shield's extension of coverage to include diagnostic x-ray provided on an out-patient basis.

The resolution referred to the Blue Shield addition of benefits for diagnostic x-ray and laboratory services rendered by doctors of medicine in the doctor's office, the patient's home or the out-patient department of the hospital when necessary to diagnose an illness or injury.

These benefits have been, or are being, added to all Blue Shield contracts. The subscriber's identification card will indicate whether his diagnostic coverage is in effect.

The action by the Radiological Society was one of a number of resolutions endorsing the Blue Shield diagnostic plan which have been adopted by medical societies throughout the state in recent months.

INTRODUCE "HOW'S YOUR HEALTH?" TO YOUR NEWSPAPER EDITOR

Each week nearly 650 Minnesota daily, county and suburban weekly and semi-weekly newspapers receive the health column "How's Your Health?" In addition, more than fifty Minnesota radio and television stations are on the regular mailing list of the weekly health feature produced by the Public Health Education Committee of the Minnesota State Medical Association.

Titles of columns released during January and February of 1960 include the following: "A Periodic Checkup is Your Health Inventory"; "Ulcer Prevention Fundamentals Explained"; "Mouth Sores Tell a Story of Health"; "ABC's of Eye Care Explained"; "Steps Listed For Saving Child from Plastic Suffocation"; "Heart Attack Patient Profile Given"; "Food Likes—Dislikes Reveal Personality Traits"; and "False Myths Cloud Facts of Life."

Eight Minnesota newspapers have used all columns released to date in 1960. They are: *Blue Earth Register, Butterfield Advocate, Hutchinson Leader, Minneapolis Progress-Register, Pierz Journal, Waseca Journal, Watertown News* and the *Winsted Journal.*

Individual physicians and county medical societies may wish to introduce this health information service to newspapers not yet using the "How's Your Health" series.

Some of the newspapers which print "How's Your Health," do so as a column, others print the material as a straight news story.

Interested editors should be advised to look for "How's Your Health" in the weekly packet of news releases mailed to all members of the Minnesota Editorial Association.

Sample copies will be mailed from the Minnesota State Medical Association offices upon request.

TV VIEWERS SEE "WHAT'S IN THE DOCTOR'S BAG"

Television viewers in the Twin City area had the opportunity on the evening of February 11, of discovering just what really is in the doctor's bag. Dr. Robert Semsch and Dr. James Rogers Fox, both members of the Public Health Education Committee of the Minnesota State Medical Association appeared on the program. The participants presented an informal explanation of the use and purpose of the most common diagnostic instruments found in the doctor's bag. A fully equipped physician's bag was furnished by Physicians and Hospitals Supply Company, Minneapolis. Other properties used in the production of the show were furnished by the University of Minnesota Hospitals, Minneapolis, the Veterans Administration Hospital, the Minnesota Heart Association and the American Medical Association. At the conclusion of the show, Family Health Records were offered to the television audience.

CLINICAL MEETING FILM AVAILABLE

The 13th Clinical Meeting of the American Medical Association in Dallas, December 1-4, 1959, can be brought back to life on your movie screen.

Some of the important scientific developments presented at the meeting have been preserved on a 16mm sound film which is now available to you and your program chairman.

Selected highlights of the lectures, exhibits and discussions make an informative

twenty-five-minute motion picture. Dr. Oscar Auerbach is seen during an interview on his widely discussed study, linking smoking and lung cancer. Dr. Hubertus Strughold gives his views on medicine and man in space, and, on the lighter side, there is an amusing look at turn-of-the-century medical journals and vintage cars.

For the physician who attended the meeting, the film gives an overall view of the happenings and will recall significant points and bring back many pleasant memories. For those who were unable to attend, the film offers a way to bring the meeting in capsule form to them and to provide a sense of actual participation.

In brief, the film offers an excellent opportunity for physicians to learn more about the variety of scientific subjects discussed during this outstanding scientific program.

This motion picture, produced by Fordel Films of New York for the Schering Corporation and the American Medical Association, was designed to be shown during state and county medical society meetings and at hospital staff meetings.

You can reserve your copy for your next meeting by writing to the Film Library, American Medical Association, 535 North Dearborn Street, Chicago 10, Illinois. Your only expense is the return postage on the film.

"REHABILITATION ADDS LIFE TO YEARS"

A new and timely scientific motion picture prepared by the American Medical Association—points up the role of the physician in initiating and directing community rehabilitation programs.

Actual case histories dramatically illustrate various types of rehabilitation problems met by physicians in practice—the hemoplegic housewife . . . the factory worker with the injured hand . . . the coronary victim.

Emotional, social and economic factors surrounding a patient's disability must be looked after as much as his mental and physical needs. Because of this, local medical societies should list the services available in the community. Such services include convalescent homes, employment groups, visiting nurses, social agencies, protective workshops, speech clinics, vocational guidance groups, hobby and handicraft clubs, and so on.

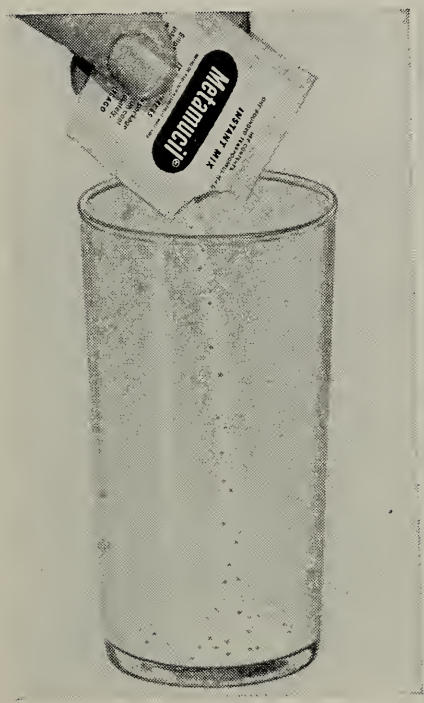
"Rehabilitation Adds Life To Years" was developed by the Committee on Rehabilitation, American Medical Association, to stimulate physician interest in total patient care. Plan today to show this thirty minute, color, sound film at local medical society and hospital staff meetings. Know the rehabilitation services in your area. Under your direction, rehabilitation programs can play a vital role in the lives of your disabled patients.

Available (for return postage only) from the Film Library, American Medical Association, 535 North Dearborn Street, Chicago 10, Illinois.

INFLATION HITS COST OF LETTER WRITING

The cost of business letters has risen. The current estimate is $2.00 per letter. With this knowledge at hand, many physicians may wish to re-evaluate their business letter writing habits. A number of authorities in the art of business letter writing now recommend the adoption of a style which comes more quickly to the point, in shorter letters, less formal in nature. The following ten-point plan for business letter improvement was suggested in the April 1959 issue of *Office Executive* magazine.

1. *Learn* to write by doing. . . . Get plenty of directed writing practice. . . . 2. *Try* to write in a conversational tone—but don't ramble. . . . 3. *Forget* useless and out-moded business jargon and write naturally. . . . 4. *Get* a good reference book on writing (we recommend "Ten Commandments for Writing Letters that Get Results" by Donald R. Roberts of Western Girl Inc., and John P. Riebel—$6.00—Ask for it at your book store.)



5. *Review* the fundamentals of good English. Find out what constitutes a good sentence and aim to upgrade your vocabulary. . . . 6. *Organize* your thoughts before writing. 7. *After* you have written something, analyze it and then rewrite it. . . . 8. *Periodically* audit the letters you have written to see whether you can improve your writing pattern. . . . 9. *Ask* someone else to criticize your letters. Another person can spot your errors more easily than you. . . . 10. *Try* a simple do-it-yourself test. . . . Read your letters aloud to determine whether they are really YOU who are talking in them.

VETERANS ADMINISTRATION-MEDICAL SCHOOL RELATIONSHIPS

The AAMC Committee on Veterans Administration-Medical School Relationships recently requested the deans of the United States medical schools to fill out a questionnaire on the extent of current use of and projected needs for Veterans Administration Hospitals by medical schools in their educational and research programs. Each of the 82 four-year medical schools replied. It was found that 71 medical schools participate by means of the Dean's Committee in the operation of 96 VA hospitals.

To what extent are the VA hospitals used for undergraduate education? The data from the questionnaire on this point are summarized in Table I.

In the area of graduate medical education, it was found that 67 VA hospitals participate in residency training programs which include a total of 1,381 positions: 467 of these positions connected with 44 medical schools are in the area of medicine; 561 positions connected with 52 schools are in surgery; 150 positions connected with 27 schools are in psychiatry; and 203 positions connected with 32 schools are in other clinical areas.

One of the problems which impedes the utilization of certain VA hospitals for medical education is geographical distance from the medical school. The usable data on this point indicates that 33 hospitals, or 38.4% of the VA hospitals are adjacent to the medical school using their facilities; twenty-seven (31.4%) of the VA hospitals are within fifteen minutes by car from the medical school; and twenty-six (30.2%) of the total are more than fifteen minutes travel by car from their respective medical schools.

Finally, the Committee was interested in learning the value of the VA hospitals to the medical schools. First, the deans of the medical schools were asked to rate the value of the VA hospitals they worked with to the medical schools' various programs. The results are indicated in Table II.

A second way in which the deans estimated the value of the VA hospitals to the medical school pro-

(Continued on Page A-60)

> This Section is for you to voice your convictions, comments, and queries on all subjects political, economic, historic, humorous, scientific or otherwise, to many physicians. Writings not sufficiently formal and too brief for an editorial or a scientific manuscript are requested. Clinical and research observations, no matter how brief, similar to those in *The Lancet* (London), are particularly encouraged.

TABLE I. LENGTH OF TIME AND NUMBER OF MEDICAL STUDENTS RECEIVING INSTRUCTION IN VA HOSPITALS

Discipline	2nd Year			3rd Year			4th Year		
	Number of Schools Participating	Average Number of Students Per School	Average Number of Days in Hospital Per Student	Number of Schools	Average Number of Students	Average Number of Days in Hospital	Number of Schools	Average Number of Students	Average Number of Days in Hospital

VETERANS ADMINISTRATION-MEDICAL SCHOOL RELATIONSHIPS

(Continued from Page A-56)

grams was in terms of replacement cost. The data indicated that 351 additional staff members would be needed in the medical school faculties; $1,997,500 additional funds would be needed in medical school budgets; and facilities for 15,850 out-patient visits per year and 4,395 beds for in-patients would be needed if VA hospitals were not available for use in the various programs of medical education.

It would appear from these data that it is the judgment of the deans of American medical schools that the Veterans Administration Hospitals comprise an important segment of the facilities which are currently used to carry on medical education in the United States.

ASSOCIATION OF AMERICAN
MEDICAL COLLEGES

DOCTOR-HOSPITAL ADMINISTRATOR RELATIONSHIP

Admiral Rickover's conception *(Saturday Evening Post,* February 13) of Doctor-Hospital Administrator relationship is ideal. Would that this were practiced.

Hospital administration, like any administrative organization, obeys Parkinson's first law* This is clearly illustrated, although transparently disguised, in the article "The Patient Gets a Break" *(Post,* January 2).

To wit:

1. Mr. Carl Ave'Lallemant speaks of "his patients." Mr. Ave'Lallemant is not a physician.
2. There is no mention of any direction by physicians in the article; only administrators and their minions.
3. Statistics show one patient in five is desperately ill and one should be ambulatory. (The abuse of hospital facilities might be investigated.)
4. "We chose our nurses for their warmth and patience. Often at night a patient sits late over coffee with the nurse talking out his fears." (Who orders coffee for "his patients" late at night?)
5. His fifth unit, Extended Care, carries hospital administration into the home.

This Progressive Patient Care business has the hallmarks of a bid by the hospital administrators to control the practice of medicine. Already some administrators in St. Paul have blantantly attempted to gain control of the practice of Pathology and Radiology, both among hospitalized patients and on an outpatient basis. This is just a step in the establishment of control of general medical practice.

Perhaps the objectives of lay hospital administrators should be investigated. This investigative organization would, of course, follow Parkinson's first law and so ad infintum to be fundamental betterment of patient care.

Incidently, the Minnesota Blue Cross plan, the hospital administrators' own plan, thus far follows Parkinson's second law† to the letter.

Sincerely,
JOHN W. JAMES, M.D.

Saint Paul, Minnesota
February 19, 1960

*Parkinson's First Law: In any administrative organization, subordinates will multiply in accordance with a known formula and without relation to work (if any) expected of them.

†Parkinson's Second Law: Public expenditure rises to meet an income which is assumed to be limitless, a ceiling which is not there.

More gastric acid neutralized faster...with new Creamalin

ANTACID TABLETS

ACID NEUTRALIZATION WITH LEADING ANTACID TABLETS (PER GRAM OF INGREDIENTS)[1]

Tablets were powdered and suspended in distilled water in a constant temperature container (37°C) equipped with mechanical stirrer and pH electrodes. Hydrochloric acid was added as needed to maintain pH at 3.5. The volume of acid required was recorded at frequent intervals for one hour.

GREATLY HEIGHTENED REACTIVITY to acid characterizes the action of New Creamalin Antacid Tablets.[1,2] They act faster and longer than other leading tablets and neutralize considerably more acid.[1] These tablets provide virtually the same effects as a liquid[2] with the convenience of a tablet. New Creamalin tablets give faster, greater and more prolonged relief.

NOT CONSTIPATING, New Creamalin Antacid Tablets will not produce "acid rebound" or alkalosis. They have a pleasant taste.

Creamalin, trademark reg. U. S. Pat. Off.

EACH NEW CREAMALIN ANTACID TABLET contains 320 mg. of specially processed, highly reactive, short polymer dried aluminum hydroxide gel (stabilized with hexitol), with 75 mg. of magnesium hydroxide.

Adult dosage: Gastric hyperacidity—2 to 4 tablets as necessary. Peptic ulcer or gastritis—2 to 4 tablets every two to four hours. Tablets may be chewed, swallowed whole with water or milk, or allowed to dissolve in the mouth.

How Supplied: Bottles of 50, 100, 200 and 1000.

The Physician's Diary

At the recent annual meeting of the medical staff of St. Mary's Hospital, Duluth, **Dr. Robert H. LaBree** was named chief-elect. **Dr. A. O. Swenson** was installed as **chief of staff, succeeding Dr. S. S. Houkom. Dr. William M. Spang** was elected secretary of the medical staff. Receiving honorary life memberships on the staff were **Dr. C. L. Haney, Dr. M. A. Nicholson, Dr. O. E. Sarff, Dr. D. F. Pennie,** and **Dr. D. W. Wheeler.** Elected to the executive committee as chiefs of clinical services for two-year terms were **Dr. W. A. Klein,** Orthopedics; **Dr. K. E. Johnson,** Obstetrics and Gynecology; **Dr. John B. Moyer,** Medicine; **Dr. J. H. Leak,** Eye, Ear, Nose and Throat; **Dr. M. M. Fifield,** Urology; and **Dr. R. J. Eckman,** General Practice.

* * *

Governor Orville Freeman has re-appointed **Dr. Harold A. Wente,** Rochester, to the Minnesota State Board of Health. **Dr. Frank H. Krusen,** Rochester, is president of the Board. His term expires January 1, 1961.

* * *

The Family Nursing Service of St. Paul recently honored **Dr. Robert Rosenthal** and **Dr. Lillian Nye** at their 24th annual meeting. The awards were presented for the doctors' participation in the Red Feather Agency for more than thirty years.

At a recent meeting of the nurses staff of St. Joseph's Hospital, Brainerd, **Dr. Joseph Marvin** gave a talk on Obstetrics and Gynecology.

* * *

The Renville County Hospital Board elected officers at the Board's recent annual meeting. **Dr. Leo Furr,** Bird Island, is chief of the medical staff.

* * *

Members of the Knight Youth Club of Cold Spring recently heard **Dr. John P. McNamara** speak on "A Psychiatrist's Secrets for Success." Doctor McNamara is medical director of the Central Minnesota Mental Health Center.

* * *

Dr. John A. Anderson, University Medical School professor and Head of the Department of Pediatrics, recently directed a course in pediatrics for general physicians held at the Center for Continuation Study at the University.

* * *

A practicing Minneapolis pediatrician for more than forty years, **Dr. Lawrence Richdorf,** was honored recently as A Venerable Old Pediatrician (VOP) by the "young upstarts" of the profession. Qualifications for the honor include being over sixty-five and having practiced in the

community for more than twenty-five years, according to **Dr. Lawrence F. Erickson,** Master of Ceremonies. Among those on hand to salute Doctor Richdorf were his first patient, **Dr. Harold Mork,** Anoka; Tom Cook, secretary of the Hennepin County Medical Society, and **Dr. John Anderson,** Head of Pediatrics at the University of Minnesota.

* * *

A paper entitled "Surgical Treatment of Diffuse Spasm of the Esophagus" was presented recently at a four-day sectional meeting of the American College of Surgeons in Boston by **Dr. F. Henry Ellis, Jr.,** of the Mayo Clinic. More than 4,000 surgeons and nurses attended the session.

* * *

Dr. Herbert L. Huffington, Jr., Waterville, has been appointed County Health Officer of Le Sueur County for 1960.

* * *

Members of the Southern Minnesota Academy of General Practice recently heard **Dr. Lyle A. French,** University of Minnesota brain surgeon, and **Dr. Malcolm McCannel,** University of Minnesota eye specialist, describe the latest in treatment of cataracts.

* * *

It has been announced that the Hibbing General Hospital medical staff has elected **Dr. J. W. Raattama,** Hibbing, president of the staff. Also elected at the annual meeting of that group were **Dr. K. E. Ahola,** vice president, and **Dr. J. J. Muller,** secretary.

A short ceremony was held recently in memory of **Dr. Winchell McK. Craig,** retired Head of the Section of Neurologic Surgery, Mayo Clinic, who died in February. **Dr. Charles A. Owen, Jr.,** presided at the ceremony. **Dr. Henry W. Woltman,** a longtime friend of Doctor Craig, read a tribute to Doctor Craig, and **Dr. Thomas B. Magath,** retired Rear Admiral in the Medical Corps of the U. S. Naval Reserve, read a tribute written by Rear Admiral B. W. Hogan of Washington, D. C., Surgeon General of the U. S. Navy. **Dr. Howard F. Polley,** Mayo Clinic, represented Ohio Wesleyan University. Doctor Craig had been a member of the Board of Trustees of Ohio Wesleyan for a number of years.

* * *

Dr. V. K. Funk, medical director of Glen Lake Sanatorium, has announced that the Sanatorium has received approval by the American Medical Association to establish a residency program in thoracic surgery. **Dr. James Seay** will fill the residency position. The approval has the consent of the American Board of Thoracic Surgery.

* * *

Members of the St. Olaf Hospital Auxiliary, Austin, heard **Dr. Paul C. Leck** give an address entitled "Rural Zoning and Sanitation," at a recent meeting.

* * *

A member of the Minnesota Department of Health, **Dr. Helen Knudsen,** recently spoke to a subcommittee of Community Chest senior citizens committee on licensing standards and the use of small nursing homes. The

effective in and simplifies
the management of
stable adult diabetes

"In our experience the action of DBI on the adult stable type of diabetes is impressive... 88% were well controlled by DBI."[2]

"Most mild diabetic patients were well controlled on a biguanide compound [DBI]... regardless of age, duration of diabetes, or response to tolbutamide."[3]

"DBI has been able to replace insulin or other hypoglycemic agents with desirable regulation of the diabetes when it is used in conjunction with diet in the management of adult and otherwise stable diabetes."[4]

well tolerated — On a "start-low, go-slow" dosage pattern DBI is relatively well tolerated. DBI enables a maximum number of diabetics to enjoy the convenience and comfort of oral therapy in the satisfactory regulation of...

subcommittee was organized to study problems arising from the new state law lowering payments given to unlicensed nursing homes.

* * *

At the 62nd annual meeting of the Psi Chapter of the Alpha Kappa Kappa medical fraternity, **Dr. A. C. Kerkhof**, Minneapolis, president of the Minnesota Heart Association, was given honorary membership. Honorary membership is awarded for distinguished medical and community leadership, and adherence to the "highest standards of medical practice." The award has been granted only nine times.

* * *

Dr. R. O. Sather, Crookston, was guest speaker of the Rotary Club at a recent noon luncheon. His subject was on "Heart Disease, Its Causes and Its Treatment."

* * *

A new Mayo Clinic heart study laboratory is nearing completion at St. Mary's Hospital, Rochester. The new laboratory, which will be used in the diagnosis and study of diseases and defects of the heart and circulatory system, will be staffed by four physicians, five technicians and a secretary. The physicians are **Drs. H. J. C. Swan, George D. Davis, O. W. Kincaid**, and **E. A. Moffitt.** The laboratory consists of two patient study rooms, a recording room, an x-ray control room, a blood-gas laboratory, a patient recovery room, a darkroom, a conference room, and offices for Doctor Swan and the laboratory supervisor.

As guest speaker at a Duluth Dental Society dinner, **Dr. William Martin**, Duluth cardiologist, recently spoke on coronary thrombosis cases. Doctor Martin explained how early detection of heart disease is possible through modern techniques and discoveries.

* * *

Members of the Albert Lea Lions club recently enjoyed a program provided by **Dr. H. B. Neel**, an Albert Lea surgeon. Doctor Neel described the foundation of the American College of Surgeons in 1913 and the role it plays in maintaining standards for the specialty, and went on to explain the history of surgery. He then showed a film, "The Hands We Trust," which was a narrative film on the training and studies required of a surgeon.

* * *

Dr. Mancel T. Mitchell has been elected chief of staff of St. Barnabas Hospital, Minneapolis, by the hospital's medical staff. **Dr. Charles A. Aling** was elected vice chief of staff and **Dr. Donald G. Bohn**, secretary.

* * *

Marshall physician, **Dr. Wayne Taintor**, has received a certificate of approval from the American Board of Abdominal Surgery to perform abdominal surgical work. The announcement came from Dr. Blaise F. Alfano, of the American Board of Abdominal Surgery.

* * *

Two members of the Mayo Clinic staff have been elected fellows of the American College of Radiology.

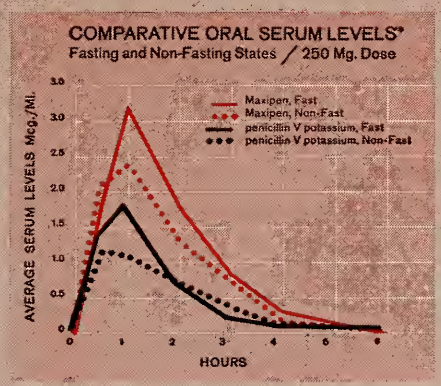
MAXIPEN®

α-phenoxyethyl penicillin potassium

THE ORALLY MAXIMAL PENICILLIN

Maximal Absorption

Acid stable, highly soluble



Maximal Blood Levels

Maximal Flexibility

May be administered without regard to meals. However, highest absorption is achieved when taken just before or between meals.

Maximal Oral Indications

Indicated in infections caused by streptococci, pneumococci, susceptible staphylococci, and gonococci

*Based on 3294 individual serum antibiotic determinations. Complete details available on request.

DOSAGE: For moderately severe conditions, 125 to 250 mg. three times daily. For more severe conditions, 500 mg. as often as every four hours around the clock.

NOTE: To date, MAXIPEN has not shown less allergic reactions than older oral penicillins. Usual precautions regarding penicillin administration should be observed.

SUPPLIED: MAXIPEN TABLETS, scored, 125 mg. (200,000 units), bottles of 36; 250 mg. (400,000 units), bottles of 24 and 100 tablets. MAXIPEN FOR ORAL SOLUTION; reconstituted each 5 cc. contains 125 mg. (200,000 units), in 60 cc. bottles.

MAXIPEN, the orally maximal penicillin, is a triumph of man over molecule; a product of Pfizer Research

Science for the World's Well-Being

(Continued from Page A-74)

They are **Dr. John R. Hodgson,** consultant in radiology, and **Dr. David G. Pugh,** consultant in the section of roentgenology. The doctors received degrees from the college at the Convocation recently during the Annual Meeting of the College in New Orleans. Elevation to fellowship in the college is based on outstanding contributions and service to radiology and follows election by all present college fellows.

* * *

Among the many talks given recently on heart disease, **Dr. John Meinert,** Willmar spoke on that subject to the Willmar Kiwanis Club at a noon luncheon. Doctor Meinert also distributed some pamphlets to the Kiwanians on the subject of heart disease.

* * *

Newly elected officers of the University of Minnesota Medical Alumni Association have been announced as follows: **Dr. Charles J. Beck,** North St. Paul, first vice president; **Dr. Neil M. Palm,** St. Paul, second vice president; **Dr. Robert H. Monohan,** St. Paul, treasurer; and **Dr. Sheldon M. Lagaard,** Minneapolis, president.

* * *

The Society of University Surgeons, an organization of teaching surgeons from the nation's leading medical schools, recently met in Minneapolis. The University of Minnesota medical school acted as host, with **Dr. Bernard Zimmermann** of the University's surgery staff in charge of arrangements.

Dr. J. B. Gaida, St. Cloud, spoke on causes, treatment and prevention of handicapped hearing during a public health nurses conference at St. Cloud. Approximately thirty-five public health nurses attended the one-day conference.

* * *

Members of the Hiawatha Valley Chapter of the National Paraplegia Foundation heard **Dr. Frank E. Krusen,** Mayo Clinic, speak on the progress of physical medicine and rehabilitation.

* * *

The Austin Clinic staff has announced the appointment of **Dr. John C. Patten** to the Clinic. Doctor Patten is a graduate of the University of Vermont Medical School, and recently completed a five-year surgical residency at Lenox Hospital in New York.

* * *

Dr. Owen Wangensteen, Chief of Surgery at the University of Minnesota Medical School, addressed the Society of University Surgeons when it met in Minneapolis. Doctor Wangensteen spoke on research and its vital importance to medical schools.

* * *

The Doctor's Committee of the LeCenter Community Club has announced that **Dr. Homer H. Russ,** formerly of St. Paul, will establish a general medical practice in LeCenter beginning July 1, 1960. Doctor Russ recently completed his internship at Bethesda Hospital, St. Paul, and received statewide publicity for an emergency heart massage that saved the life of a Roseville, Minnesota, infant.

A MODERN PRIVATE SANITARIUM

for the Diagnosis, Care and Treatment of Nervous and Mental Disorders

MAIN BUILDING—One of 8 Units in "Cottage Plan"

ST. CROIXDALE ON LAKE ST. CROIX

PRESCOTT, WISCONSIN

Located on beautiful Lake St. Croix, 18 miles from the Twin Cities, it has the advantages of both City and Country. Every facility for treatment provided, including recreational activities and occupational-therapy under trained personnel. Close personal supervision given patients, and modern methods of therapy employed. Inspection and cooperation by reputable physicians invited. Rates very reasonable. Special rates given to custodial patients.

Book Reviews

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical Libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

PRACTICAL PROCTOLOGY. 2nd edition. By Louis A. Buie, M.D., F.A.C.S., Emeritus head of the Section of Proctology of the Mayo Clinic, and Emeritus Professor of Proctology in the Mayo Foundation, Graduate School, University of Minnesota. 737 pages, 280 illus. Price $22.50. Springfield, Illinois: Charles C Thomas. 1960.

The first edition of Practical Proctology was published in 1937, and very shortly was out of print. It was a book of only 512 pages and 152 illustrations and it contained no color plates, whereas the new edition has twenty illustrations in color. For approximately twenty years, no copy of the first edition of *Practical Proctology* has been available at either bookstores or the publisher.

The new edition of Dr. Buie's book begins with the responsibility of the physician, proceeds through embryologic and anatomic considerations, preoperative and postoperative care and anesthesia, infection and the various conditions which may be encountered by the proctologist. Diagnosis and methods of treatment are based on some forty years of the author's experience in this specialty of medicine. "It was he who guided and nurtured this specialty in its early formative years and who is a guiding spirit in its present adulthood," Dr C. W. Mayo comments in the foreword.

In other respects, the book emphasizes the deep devotion to the art of practicing medicine which Dr. Buie has advocated throughout his career. This portion of the book has to do with reassuring the patient, quieting his fears, assisting him as much as possible to ensure a successful examination, relieving his pain and discomfort explaining to him what is to be done and why, and so arranging the program of treatment that the economic status of the patient will not be subjected to needless strain.

ANESTHESIA FOR INFANTS AND CHILDREN. Robert M. Smith, M.D., Anesthesiologist, Children's Medical Center, Boston, Massachusetts. 418 pages. Price, $12.00. St. Louis, Missouri: C. V. Mosby Company, 1959.

Dr. Robert M. Smith, as Anesthesiologist at the Children's Medical Center, Boston, has had a vast amount of experience with pediatric anesthesia. He has combined his clinical experience with well-chosen academic material to provide an excellent coverage of the subject.

The subject matter has been organized into thirty-one chapters. Each chapter is headed by a list of materia covered. The book is amply illustrated with diagrams lists, graphs, and black and white photographs.

The reader is led from the basic requirements fo pediatric anesthesia through the following groups c subject material: basic physiology of infants and chi

lren; preoperative preparation of the patient; descrip-ions and discussions of various procedures and tech-iques, first in general terms and then as applied to pecific types of surgery (neurosurgery, orthopedic sur-gery); and the postanesthetic care of the pediatric sur-gical patient.

The odds and ends of the subject have been well or-ganized into chapters at the end of the book entitled: Special Problems in Pediatric Anesthesia, Fluid and Blood Replacement, Anesthetic Complications, Oxygen Therapy, Mortality in Pediatric Surgery and Anesthesia, and The Legal Aspects of Pediatric Anesthesia.

This book is of interest primarily to anesthesiologists. All physicians, however, who are concerned with in-ants and children undergoing surgery will find the irst five chapters covering basic pediatric physiology and the preparation of the patient for anesthesia of nterest and value. Chapters 24 and 25 will be of qual or greater interest. These chapters cover Anes-hesia for Minor and Emergency Surgery and Special Problems in Pediatric Anesthesia.

In the reviewer's opinion, this is the best book to be published on the subject of pediatric anesthesia to date.

RUSSELL W. BAGLEY, M.D.

THE TREATMENT OF STAPHYLOCOCCAL DIS-EASES. Edited by Henry Welch and Maxwell Fin-land. Price, $4.50, cloth. New York: Medical Ency-clopedia, Inc., 1959.

GENERAL INFORMATION

Authors

Manuscripts should be addressed to Arthur H. Wells, M.D., Editor, 915 East First Street, Duluth 5, Minnesota. Telephone RA 7-6636 or JA 5-2319. Original papers prepared for publication solely in Minnesota Medicine will be considered by the Board of Editors providing they fulfill the following editorial standards. Manuscripts should be typed double spaced on white paper with at least 1-inch margins. The original (not a carbon copy) is requested. The title on the first page should be under six words if possible or divided into two parts. The author should give his highest degree, his institutional position or his relationship to a hospital or medical organization which he may be addressing. Pages should be numbered consecutively and the author's last name should appear at the top of each page.

Bibliographical references should appear on a separate sheet entitled References. They should appear and be numbered consecutively in the order in which they first occur in the text (not alphabetically). Citations in the text require reference numbers if the author's or authors' names are not used or if there is more than one reference to the same author or group of authors. All references to author should appear in the list of References and no references should be included which are not in the text. The style and exact punctuation used in the J.A.M.A. references are requested. Journal references should include: *Author's last name, initial., initial.: title of paper. Abbreviated name of journal, volume number: page, year.* Book references should give author, title, edition number, city, publisher and year.

Illustrations (photographs, tables and graphs) should be submitted separately and not combined in the text. There should be a separate sheet entitled "Illustrations" which contains the various types of illustrations listed separately and numbered in the order in which they appear in the text. All photographs must be in black and white, clear cut, contrasting, and on glossy stock. Instructions for combining photographs are acceptable. Any number of illustrations over 4 are charged to the author. Combinations of photographs up to one-half page (6 x 4⅜ inches) count as 1 illustration.

Readers and Reviewers

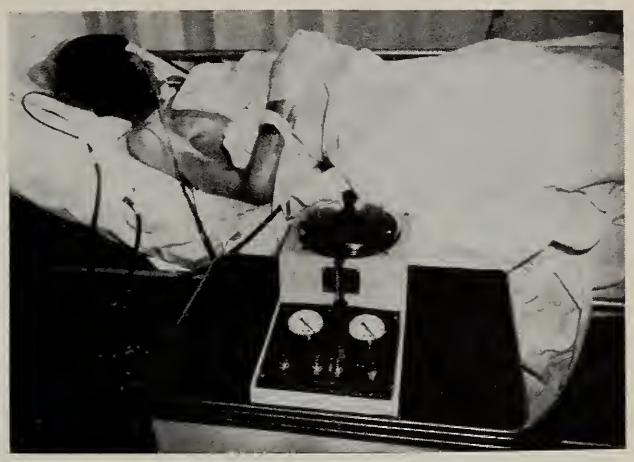

Fig. 1. Pump-refrigeration unit used for local gastric cooling.

Local Gastric Hypothermia in the Treatment of Massive Upper Gastrointestinal Hemorrhage

With a Discussion of Techniques

W. O. GRIFFEN, JR., M.D., P. A. SALMON, M.D.,
A. CASTANEDA, M.D., D. NICOLOFF, M.D.,
O. H. WANGENSTEEN, M.D.

Minneapolis, Minnesota

From the Department of Surgery, University of Minnesota Medical School, Minneapolis 14, Minnesota.

EXPERIMENTAL work has demonstrated that local hypothermia of the stomach (15° C.) reduces gastric secretion markedly, completely inhibiting the digestive action of any gastric juice secreted.[1] The reduction of the digestive capacity of the gastric juice is dramatically demonstrated by the fact that small frogs with an attached oxygen line, placed within the stomach of larger frogs or dogs undergoing gastric cooling, are able to survive for prolonged periods of time, up to thirty-six hours.[2] The blood flow through the cooled dog's stomach (15° C.) measured by determining the venous outflow was found to be only one-third of normal.[3] Since constantly monitored blood pressure did not change, the assumption is that a concomitant reduction in arterial blood flow also occurs. It is the purpose of this paper to relate some of our experiences with local gastric

cooling in the control of massive gastric hemorrhage.

Apparatus

The special materials necessary for achieving effective local gastric hypothermia are a cooling unit similar to the one used in the standard home

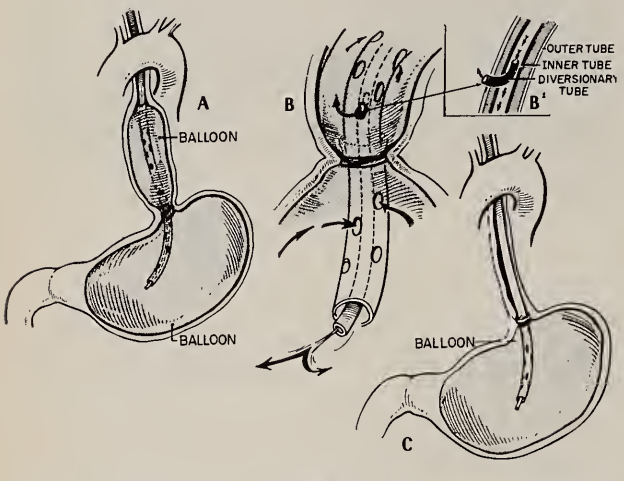

Fig. 2. Position of the balloon in the closed perfusion method. (A) Local hypothermia of the lower esophagus and stomach. (B. and B[1]) Details of the inflow and outflow of coolant to the esophageal balloon. (C) Local gastric hypothermia alone.

refrigerator, a reservoir, and a centrifugal water pump, which is capable of delivering at least 1 liter per minute.[1] A plastic catheter (1755 Bard & Company) with an outside diameter equivalent to a No. 18 French nasogastric tube will suffice as the outer outflow tube. A No. 260 polyethylene catheter is used as the inflow tube with a simple thin-walled dime-store latex balloon to receive the cooling fluid.

The refrigeration unit, reservoir, and water pump have been combined into a single mobile unit. Earlier units, with a gravity outflow system, relied on the level of fluid in the reservoir to activate the pump. The disadvantages of this system are the slower flow created by the use of gravity outflow and the alternating size of the intragastric balloon. A newer model, utilizing suitable valvular mechanisms, is a completely closed system and the fluid pumped into the balloon is replaced by a similar volume into the reservoir (Fig. 1).

Techniques

We have employed two techniques in obtaining local gastric hypothermia (Figs. 2 and 3). Our earlier and larger experience has been with a closed perfusion system employing an inlying gastric balloon attached to the double lumen tube. Under these conditions, a second nasogastric tube is necessary to maintain decompression of the stomach, to flush out blood or clots accumulating within the stomach and to provide evidence on whether the gastric bleeding continues or stops. The coolant fluid, a 30 per cent alcohol-water mixture, is pumped directly into the balloon which is inflated to a size adequate to fill the stomach without giving the patient discomfort. In this technique, the fluid must be perfused into the balloon at a temperature of —5° C., in order to obtain the ideal gastric wall temperature of 15° C. Experimentally, by using large tubing, not clinically feasible, to increase flow rate or by allowing the body temperature to drift to 30-32° C., a gastric wall temperature of 10-15° C. can be achieved with an aqueous perfusate at temperatures above the water freezing level.

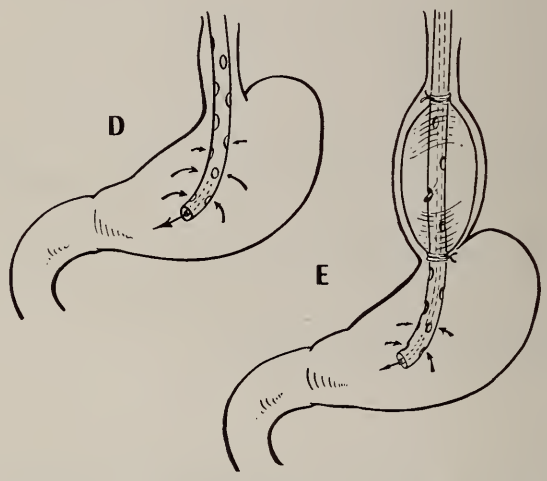

Fig. 3. Position of the tube in the open perfusion method. (D) Local gastric hypothermia. (E) Proposed method of achieving lower esophageal cooling by the closed technique combined with open gastric perfusion.

The advantage of the closed perfusion technique is that this system does operate smoothly once the tubes are in place; moreover, there can be no absorption of perfusate. The disadvantages lie in the difficulty encountered when placing the tubes and the circumstance that the patient must support the annoyance of two inlying tubes.

The alternate technique is the "open" perfusion method. Here, the double lumen tube is merely passed into the patient's stomach and the stomach

acts more or less as the balloon. In other words, fluid is perfused directly into the lumen of the stomach and accumulated blood and clots are washed out directly. This cooling scheme is more efficient and an inflow fluid at 5° C. will maintain the gastric mucosa at a temperature of 15° C. A number of coolants for this purpose have been employed; the best agent to date has proved to be a calcium-low milk (for example, S.M.A., Similac, Probana, et cetera). An earlier study in the dog indicated that local gastric cooling (15° C.) virtually closed the pylorus. In the cool stomach of man, the pyloric outflow is somewhat greater than in the dog. The advantages of this method are its ease of institution, and the possible nutritive effect the patient may receive from absorption of some of the milk during the perfusion.

A disadvantage of the method is that, although the pylorus is "closed off" in the cooling process, anywhere from 100 to 180 cc. of fluid is lost per hour into the small bowel. The method is not as adaptable, therefore, as the closed perfusion method in the care of patients with cardiac or renal difficulties, or in recent postoperative patients. There has been no trouble with tracheal aspiration when the stomach alone is being perfused openly. There is, obviously, some danger of tracheal aspiration from the esophagus in the open method, if both esophagus and stomach are being perfused.

When dealing with situations suggesting the need for perfusing both lower esophagus and stomach, we have come to employ a thin-walled latex balloon (condom) for the esophagus, while using the open technique in the stomach. In the closed method, simultaneous cooling of lower esophagus and stomach is achieved by the use of two balloons. Wangensteen (1959)[4] at the Presbyterian Hospital in New York reports use of a thin-walled latex flask-shaped balloon, which permits simultaneous cooling of esophagus and stomach with one balloon. We too, following his lead, have found this balloon (625 Airship Pioneer Rubber Co., Willard, Ohio) to suit the purpose admirably in simultaneous cooling of esophagus and stomach.

Experimentally, employing radiopaque material as the circulating medium in both the open and closed systems, it has been observed that all balloon techniques fail to fill the antrum completely (Figs. 4 and 5). On the other hand, the fundus and cardiac region of the stomach are uniformly well covered by the balloon. In the dog, even with filling of the balloon to cause marked abdominal distension, the antrum was not adequately cooled.

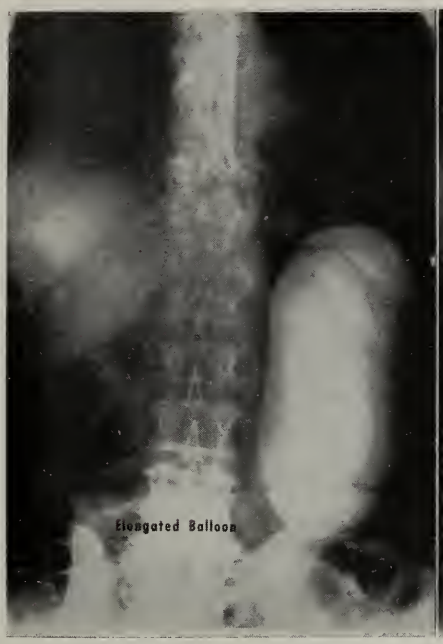

Fig. 4. The position of the 625 Airship balloon in a patient. Note the elongated neck of the balloon in place but without much flow through it, just at the esophagogastric junction.

Fig. 5. The double balloon technique for use in a patient with bleeding lower esophageal lesions. Note the extent of esophagus being cooled with this apparatus.

Fig. 6. Open perfusion of the stomach with closed cooling of esophagus, as observed in a dog.

The "open" perfusion method permits the cooling solution to reach every nook and cranny of the gastric mucosa (Fig. 6), and the important advantage of this occurrence has encouraged us to pursue the application of this technique in a larger number of our patients.

TABLE I. CONTROL OF MASSIVE GASTRIC HEMORRHAGE IN CLINICAL TRIALS

Lesion	Number of Patients	Number in Shock*	Number Controlled	Deaths Directly Due to Hemorrhage
Esophageal ulcer	1	0	1	0
Esophageal varices	5	3	4	1
Gastric ulcer	3	0	3	0
Erosive gastritis	4	1	4	0
Duodenal ulcer	13	8	13	0
Stress ulcer	4	3	3	2
Postoperative bleeding	10	5	6	1
Gastric CA	2	2	1	2
Hemorrhagic dyscrasias	2	0	1	2
Total	44	22	36	8

*Remaining twenty-two patients demonstrated Hgb. levels below 10.0 gms. together with need for rapid blood replacement to combat tachycardia, although they were not considered to be in shock clinically.

Several designs of balloons have been critically evaluated, and it would appear that the elongated balloon best meets the criteria of ease of passage and ability to cool the esophagogastric area sufficiently. It may be that the open perfusion of the stomach with closed perfusion of the esophagus will become the method of choice adaptable to all bleeding situations with the most comfort for the patient (Fig. 3e).

In further experiments, it has been noted that intragastric tension decreases during cooling, a reflection of the hypomotile state of the stomach.[5] At a gastric wall temperature of 10° C., the average intraluminal tension is reduced 6 cm. of water. Thus cold per se and not tamponade is the chief effect in stemming hemorrhage.

Indications and Contraindications

Our experience is still not sufficient to state that every patient with massive upper gastrointestinal bleeding is a suitable candidate for this type of treatment. Generally, the patients treated thus far have been those who have failed to respond to the usual methods of treatment and who continue to have massive hematemesis, despite the usual conservative measures of sedation, transfusion, nasogastric suction or a milk drip. The criteria we have employed as guides to invoke local gastric cooling for the control of massive gastric hemorrhage are two or all of the following: (1) shock, (2) continuing hemorrhage with a hemoglobin value of less than 10 grams, (3) necessity to continue transfusion in order to support a falling blood pressure and to control tachycardia.

Our experience has been sufficient to suggest that patients bleeding because of blood dyscrasia or a gastric cancer, are unlikely to respond to this form of treatment. If the blood dyscrasia is correctible by suitable measures, local gastric cooling will slow the gastric hemorrhage, thereby serving as an adjuvant measure in controlling the gastric bleeding temporarily.

Results

Our experience now totals forty-four patients. The current results follow pretty much the pattern of an earlier report.[6]

Gastroduodenal Ulcers and Erosive Gastritis

Approximately half the patients fall into the category of gastroduodenal ulcers and erosive gastritis, which group respond well to the use of local gastric hypothermia. Of this group, six were eventually operated upon; one 5 hours after cessation of hemorrhage, one almost a year after the control of hemorrhage by local gastric hypothermia.

A few representative case records will serve to give information concerning use of local gastric cooling in peptic ulcer.

Gastric Ulcer—Mrs. M. L., aged sixty-three, was admitted to this hospital in May, 1958, following two prior episodes of massive hematemesis with tarry stools and a long history of symptoms suggestive of duodenal ulcer, although this diagnosis had never been substantiated by barium studies. Bright red blood was readily obtained from the nasogastric tube, but she was not in shock. The patient's bleeding tests were all within normal limits, and the hemoglobin value was 9.7 gms., in spite of 1,250 ml. of blood given prior to the institution of local gastric hypothermia.

Bleeding stopped after six and one-half hours of cooling, during which time she received 1,250 additional ml. of blood, which restored the hemoglobin to 14.5 gms. No explanation for the hemorrhage was discovered despite a number of G.I. series until a year later, when a lesser curvature gastric ulcer was demonstrated by x-ray. A segmental gastrectomy was performed on May 11, 1959, for a histologically benign ulcer, and the patient recovered uneventfully.

Uremic Duodenal Ulcer.—Miss G. D., aged thirteen, with bilateral renal staghorn calculi, developed massive hematemesis with tarry stools. At the end of a four-day period of bleeding, and after having received 4,000 cc. of blood, the blood pressure dropped to 45 mm. Hg. Gastric hypothermia was carried out for 6 hours, during

which time the bleeding stopped. She received 850 ml. of blood and the vital signs stabilized.

Three days later, she again went into shock from recurrent massive gastric hemorrhage. Gastric hypothermia was reinstated and the bleeding again stopped quite promptly. With intensive antiulcer therapy, she has had no further bleeding episodes. A G.I. series performed later demonstrated "duodenitis." The patient has been able to tolerate several corrective urologic procedures since then without incident.

Duodenal Ulcer.—Mrs. B. M., aged fifty-seven, was admitted to the hospital on September 17, 1958, for recurrent ulcer. She gave a twenty-year history of epigastric pain relieved by eating. At the time of admission, she had tarry stools and shortly after admission began to bleed massively. Cooling was instituted when more conservative means failed to stop the bleeding. After seven and a half hours, she had stopped bleeding and a skim milk drip was reinstituted. She continued well until four days later, when again signs of bleeding appeared with tarry stools, small hematemesis of coffee ground material, and a few flecks of bright red blood and hemoglobin. The response to conservative management was satisfactory. The patient was operated upon on September 2, 1958 as an elective procedure (Billroth II). Recovery was uneventful and the patient has done well.

Esophageal Varices

Of the five patients with esophageal varices, four had definite control of their bleeding with use of local esophagogastric cooling. The fifth patient returned his hemoglobin to near normal levels before requiring operation to control persistent oozing of blood. All the patients had had attempts at control of hemorrhage by the use of the Sengstaken balloon without success. Our experience would suggest it is better to invoke local esophagogastric hypothermia immediately upon admission to the hospital. As was mentioned above, it is not pressure, but cooling that controls the hemorrhage. The ultimate fate of patients with intrahepatic block or portal hypertension from cirrhosis and bleeding varices is contingent upon the patient's ability to withstand definitive operative procedures. On this score, the patient with the extrahepatic block stands a better chance, because he usually has relatively normal liver function.

Esophageal Varices from Portal Hypertension.—Miss S. L., aged twenty-two, with a diagnosis of Banti's syndrome in the early 1940's, underwent splenectomy in 1943. In 1955, she underwent complete excision of the acid secreting area of the stomach with an esophagoantrostomy for bleeding esophageal varices. Upon recurrence of bleeding, a portal systemic shunt was attempted without success in 1956. Several subsequent bleeding episodes ensued requiring hospitalization and transfusion. In June of 1958, she was admitted in shock from massive hematemesis. There seemed to be no abnormalities in the clotting system. She received 4,500 ml. of blood during an unsuccessful trial at stopping hemorrhage with a Sengstaken tube. After seventeen hours of simultaneous local cooling of the stomach and lower esophagus, employing the closed technique, the hemoglobin value returned to a level of 15.1 gms. attending the transfusion of an additional 3,000 ml. of blood. She remained stable for approximately four and a half hours, when massive hematemesis recurred, followed by profound shock. Local gastro-esophageal cooling was again initiated which succeeded in stopping the bleeding. The hemoglobin rose to 14 gms. with 2,500 ml. of blood transfusion. As soon as her condition permitted, excision of the lower esophagus and antrum was performed with interposition of a jejunal loop. Since that time, there have been no further episodes of bleeding and the patient has done well.

Esophageal Varices as Result of Postnecrotic Cirrhosis.—Mrs. E. J., aged sixty-two, had hepatitis in the past with the development of posthepatitic cirrhosis and indicative liver function tests. She had had several episodes of hematemesis over the year and a half prior to this admission which was occasioned by exacerbation of bleeding. Her hemoglobin on admission was 8 gms. and her vital signs were stable. She was transfused carefully in preparation for a portacaval shunt scheduled for the morning of December 31, 1958. However, on December 30, 1958, after bleeding most of the day with replacement of 4000 ml. of blood, her hemoglobin showed no change and her vital signs deteriorated despite the presence of a tamponading Sengstaken tube. Because of this, local gastric hypothermia was instituted and carried out for twelve hours. Her vital signs stabilized and her hemoglobin rose to 14.9 gms. from 12.0 gms., with additional transfusion of 2,500 ml. of blood.

On the morning of her scheduled operation, the cooling balloon was removed and the patient underwent portacaval shunt successfully. Unfortunately, her postoperative course was complicated by severe jaundice and deranged liver function. A small enteric fistula developed during early convalescence which failed to close spontaneously despite the absence of any signs of obstruction. The jaundice slowly cleared, but the general course was downhill, and the patient succumbed three months postoperatively. Bleeding did not recur. Had the liver function been better, the recovery of the patient would have been assured.

Postoperative Bleeding from a Variety of Lesions

Postoperative bleeding, often manifested by hemorrhagic gastritis, represents a special problem. The bleeding in such patients may well be owing to stress gastritis or ulcer, imposed by trauma of an operative procedure or catastrophy. The treatment of these patients heretofore has been extremely futile, but some success attends use of local gastric hypothermia. Six of ten postoperative

patients with this complication have been controlled successfully. The urgency of the situation is apparent in that three of the four patients not controlled by cooling required operative intervention and eventually succumbed to sepsis which, together with the antecedent operation, constituted the stress that precipitated the hemorrhage.

Postoperative Bleeding.—Mr. R. B., aged fifty-six, on October 1, 1959, underwent a Billroth II gastrectomy because of a bleeding duodenal ulcer, in an outlying hospital. Subsequent obstruction of the efferent limb of the gastrojejunostomy necessitated an exploration three weeks later. A bypassing enteroenterostomy was performed and the patient soon began to bleed massively from the upper gastrointestinal tract. During the following four weeks, the patient was sustained by intravenous fluids and required 100 transfusions for recurrent episodes of bleeding. When admitted to this hospital, the blood pressure was stable, the pulse rapid, 120 or higher, the hemoglobin 9.7 gms. Frequent transfusions, the return of bright red blood from the nasagastric tube, and the poor condition of the patient dictated the use of local gastric hypothermia for the control of bleeding. Closed perfusion slowed the bleeding to a slow ooze, while the hemoglobin returned to normal. Shift to open perfusion confirmed the suspicion that the stomach was totally obstructed. Therefore, when the patient's condition stabilized, a transthoracic truncal vagotomy with intubation of the narrow efferent limb stoma through a gastrostomy opening, and a feeding enterostomy were performed on November 27, 1959. Although an anastomotic ulcer seemed likely, it was impossible through the diaphragmatic incision to ascertain exactly the nature of the obstruction or to rectify it.

The patient then did well for eight days, when massive hemorrhage attended removal of the gastrostomy tube, which had been placed through the efferent stomal outlet. Shock and a drop of hemoglobin to 10.3 gms. occurred. Closed local gastric hypothermia was successful in stopping the bleeding promptly; even so, cooling was continued for forty-eight hours. A skim milk drip demonstrated persistent outlet obstruction. Nutrition was mainained by daily enterostomy feedings of 3,000 cc. whole milk supplemented with intravenous glucose and electrolytes. On December 18, 1959, seventy-nine days following the initial gastric surgery and twenty-three days after admission here, a procedure directed at correction of the persistent outflow obstruction was undertaken. Localized abscess formation and dense adhesions made mobilization of the stomach pouch impossible. Therefore, a compromise procedure with excision of the nonfunctioning enteroenterostomy on the efferent limb, and a new enteroanastomosis between the afferent and efferent limbs was effected. Closure of the resultant 15 cm. longitudinal defect in the efferent limb was accomplished by a single layer of interrupted 5-0 sutures of silk. Continuity of the small bowel was established by an end-to-end jejunal anastomosis. A total of 153 tranfusions, that is, more than 75 liters of blood, were given to this patient during this time.

The patient survived the ordeal nicely. He was dismissed to his home on January 19, 1960. After more than two months of parenteral therapy, he was resuming use of the upper segment of the digestive tract for ailmentation. The enterostomy tube was removed on a return visit to the Out-Patient Clinic, at which time the patient was taking 2700 calories or more daily by mouth.

Postoperative Bleeding.—Mr. H. J., aged sixty-nine, had an episode of obstructive jaundice three years prior to this admission. He was treated by cholecystectomy and common bile duct exploration with removal of two stones. In one and one-half years later, his jaundice recurred and re-exploration of the subhepatic area was attempted, but abandoned because of bleeding. His jaundice relented only to recur shortly before his first admission here on August 12, 1959. All tests prior to his surgery indicated an obstructive jaundice, with normal coagulation mechanism. Re-exploration on August 14, 1959, was attended by a sizable loss of blood due to the marked vascularity of the adhesions in the subhepatic area. A gall bladder with thickened walls, but containing green bile was discovered, and there was a great deal of induration and scarring about the head of the pancreas. It was impossible to ascertain the nature of the pancreatic lesion, so a bypass cholecystojejunostomy was performed.

Postoperatively, the patient did well for four days, when he developed sudden, massive upper gastrointestinal hemorrhage and went into shock. He received 2,500 ml. of blood rapidly, but the hemorrhage continued. Local gastric hypothermia induced a rapid halt in the bleeding. The patient's vital signs stabilized and his hemoglobin rose to 14.3 gms., with transfusion of 1500 ml. of blood. He had several more episodes of hematemesis over the next four days, which were controlled adequately with frequent manual flushing of the stomach with iced saline solution. He was discharged on his twenty-second postoperative day, and has remained without bleeding to the present day.

"Stress" or Steroid Ulcers

The group of steroid or stress ulcers demands special consideration. It would appear that the so-called stress ulcer, whether gastric or duodenal, represents a special entity, somewhat apart from the usual peptic ulcer. Once hemorrhage is controlled by local gastric cooling, definitive therapy is in order. Granted the general condition permits, when bleeding has been controlled by local gastric hypothermia, such patients should undergo operation. In one patient with metastatic breast cancer, a bleeding gastric ulcer as a result of cortisone therapy, failed to respond completely to local gastric cooling. Two patients experienced rebleeding a few days following control of their initial hemorrhage. These experiences have taught the necessity of advising operation in patients who have been under steroid therapy. Rebleeding is

much more likely to occur than after cooling for a chronic duodenal or gastric ulcer.

Stress Ulcer.—Mr. D. V., aged sixteen, suffered a fracture of C-5 in a diving accident on August 1, 1958, resulting in complete quadriplegia, was being treated with Crutchfield tong traction. The admission hemoglobin was 18 gms.; sixteen days later, the patient had an emesis of coffee ground material. This was soon followed by bright red hematemesis and a decline in the hemoglobin to 7.0 gms., where it remained despite transfusion of 1,500 ml. of blood. The vital signs remained stable and all bleeding tests were normal. Because of continued hematemesis, local gastric hypothermia was instituted. The bleeding stopped and the patient's hemoglobin returned to normal with an additional 2,000 cc. of whole blood.

The patient then did quite well for four days, when massive hematemesis recurred. Cooling was reinstated and his bleeding again stopped. During this time, he received 4,250 ml. of blood and the hemoglobin reached 16.3 gms. The patient has had no further episodes of bleeding. A subsequent G.I. series showed marked spasm of the duodenal bulb. His gastric juice has demonstrated the strong digestive action characteristic of duodenal ulcer.

Can Local Gastric Cooling Accelerate Ulcer Healing?

Inasmuch as virtual suppression of gastric secretion and inhibition of peptic activity of the gastric juice can be achieved by local gastric cooling, the question naturally arises: Could the healing of ulcer craters be accelerated by the use of this method? The place, obviously, for trial of the method would be in duodenal ulcer, employing the open method of perfusion with calcium-poor milk at a temperature low enough to suppress gastric secretion, but not so low that gastric emptying would be completely arrested by an immobile pyloric sphincter. Certainly, the method deserves trial. Failure to heal peptic ulcer by conservative means is owing primarily to the circumstance that, feeding stimulates acid-peptic secretion with the result that the pH of the resultant gastric mixture at times falls well into the range of a very active peptic digestion. Lowering of the gastric temperature to suppress gastric secretion and inhibit peptic activity without obstructing outflow of the coolant employed might make an important addition to our medical armamentarium to encourage healing of ulcer defects. Moreover, the ulcer defect has to heal to complete epithelialization or the stage is set immediately again for recurrence of the ulcer and the development of a crater. Neither starvation nor feeding can inhibit gastric secretion and peptic activity. Local gastric cooling can. Very little has been added to the conservative management of peptic ulcer since Cruveilhier of Paris inaugurated frequent feedings of milk to patients with "round ulcer," more than a century ago.

Summary and Conclusions

Local gastric hypothermia has been shown experimentally to reverse many of the factors responsible for hemorrhage in the peptic ulcer diathesis. Therefore, it is not surprising to find use of local gastric hypothermia very efficacious in the management of massive gastric hemorrhage from a variety of manifestations of the peptic ulcer diathesis. It has been very reassuring, too, to note its effectiveness in the control of massive hemorrhage from esophageal varices. It has proved quite successful also in cases of erosive gastritis, which is in reality a peptic ulcer variant.

Massive gastric hemorrhage occurring postoperatively in patients is essentially a stress ulcer phenomenon. Some instances of massive hemorrhage following operation are found to be owing to hemorrhagic gastritis. Even though controlled by local gastric cooling, the tendency of recurrence is so high that operation is to be recommended, if the patient's condition permits. Moreover, hemorrhagic gastritis often demands extensive gastric resection to insure effective control of the hemorrhage. Use of local gastric hypothermia in patients suffering from gastric tumors or blood dyscrasias rarely offers complete cessation of hemorrhage.

Contamination of Milk with Penicillin

Cranberries and capons are not the only foods that may contain contaminants. It has been recognized for several years that milk may be contaminated by enough penicillin to cause reactions in persons who are unusually sensitive to the antibiotic.
The author discusses this problem and presents data regarding 609 farms in this region.

RONALD ROSANOVE, B.Sc., M.B., B.S.
Rochester, Minnesota

SENSITIVITY to penicillin is increasing in frequency and severity in the general population at an alarming rate.[1] The ever-increasing incidence of various allergic reactions caused by penicillin has made it the primary problem of drug allergy.[2] Frequent reactions and many sudden deaths from anaphylaxis following the administration of penicillin has occurred in the United States and other countries.[3] Most of these patients did not require the antibiotic as a lifesaving measure,[4] and many of them denied having received penicillin previously.[5] A W.H.O. bulletin in 1958, analyzing the data on 2,500,000 patients, each receiving from one to twenty-five injections of penicillin, revealed a reaction rate of approximately 2 per cent and fatal reactions in one of each 70,000 patients treated.[6] The use of skin tests before the administration of penicillin might aid in reducing the incidence of these reactions by revealing reactivity in highly susceptible persons.[2,5]

Welch and associates,[7] from a nationwide survey, estimated that 95 per cent of severe anaphylactic reactions and 85 per cent of other types of moderately severe reactions to antibiotics were caused by penicillin. These reactions included serum sickness, diarrhea, angioneurotic edema, urticaria and other dermatologic lesions. Welch[8] estimated that between 17,000,000 and 20,000,000 Americans may experience undue reactions to antibiotics at some time during their lives.

According to Vickers and associates,[9] many "allergic" reactions and dermatologic lesions of obscure origin may be maintained indefinitely by the ingestion of cow's milk containing penicillin as a result of the treatment of bovine mastitis. In a carefully controlled study, Zimmerman[1] showed that chronic or recurrent urticaria may be caused by the ingestion of such contaminated dairy products. The role of penicillin in these reactions was indicated by the use of penicillinase, which resolved urticaria occurring after the ingestion of dairy products or prevented such a reaction if given first.

In the Section of Dermatology at the Mayo Clinic, we have seen a twenty-three-year-old woman who had a persistent oral and cutaneous bullous eruption that simulated pemphigus vulgaris clinically and histopathologically. This eruption disappeared without specific treatment when milk and other dairy products were eliminated from the diet. Vickers and associates described acute dermatitis and a vesicular reaction in sensitive patients living on dairy farms where the milk contained up to 4 units of penicillin per milliliter. Thus, by drinking 1 liter of milk daily,

Read at the meeting of the Southern Minnesota Medical Association, Rochester, Minnesota, September 14, 1959.

The work reported in this paper was carried out under the direction of Dr. Louis A. Brunsting, Section of Dermatology, and Dr. Fordyce R. Heilman, Section of Bacteriology, Mayo Clinic.

Dr. Rosanove is a Fellow in Dermatology, Mayo Foundation, Rochester, Minnesota.

Fig. 1. Inhibition of growth of Sarcina lutea on Penassay agar by specimens of milk contained in steel cups. Note the absence of inhibition by the specimens to which penicillinase was added.

a patient unwittingly could ingest as much as 4000 units of penicillin each day.

Welch[8] reported three independent surveys on the amount of penicillin found in grocery-store samples of processed milk procured in many different locations in the United States, refrigerated and flown to Washington, D. C. These surveys disclosed the presence of penicillin in 3.2 to 11.6 per cent of the samples, the amount varying from 0.003 to 0.550 unit per milliliter. Penicillin was not found in powdered milk, evaporated milk, ice cream or butter. In a further nationwide survey in the fall of 1958 and the winter of 1958 to 1959, a total of 1170 samples of milk from the tanks of producers or from collecting trucks were tested. The presence of penicillin, confirmed by the use of penicillinase, was shown in 3.7 per cent of these samples, the concentration ranging from 0.006 to 1.22 units per milliliter. The decrease in the incidence of milk contaminated by penicillin in the various surveys was attributed to education of the farmer. It also may have been influenced by seasonal variations in bovine mastitis and by the source of the specimens.

Milk from an individual farm usually is placed into a bulk tank. Tanker trucks collect refrigerated milk from the bulk tanks of several farms, transporting this mixed milk to the dairy, where the milk is further mixed with that from other tankers in a large collecting vat before it is processed. Thus, milk containing penicillin and originating from the collecting tank of a single farm may contaminate a much larger volume of milk in the vat, although at a proportionately lower concentration. The mixed milk is distributed after rapid processing, including the "flash" method of pasteurization (165° F. for sixteen seconds), which does not destroy penicillin.

Thus, milk from one treated cow that may contain a relatively great concentration of penicillin may account for a large number of distributed whole-milk products containing penicillin at a concentration proportional to the dilution factor of the original specimen.

Method of Testing

Specimens were placed in steel cups on cultures of Sarcina lutea growing on Penassay agar. This organism is widespread in distribution, easily obtained, nonpathogenic to humans and extremely susceptible to antibiotics. It grows readily and rapidly under a wide range of external conditions. Zones of growth and inhibition can be easily

discerned and measured quantitatively on Penassay agar, which is eminently suitable for the estimation of penicillin.

Zones of inhibition of the growth of the organism showed the presence of an antibiotic (Fig. 1). Penicillin was identified by the use of penicillinase in control cups. Accurate quantitative estimation of the concentration of penicillin present was made by comparing the size of the zone on inhibition with that of controls and with a curve previously prepared with various known concentrations of penicillin.

Dairy B	395	8	—	2	0.02-0.07
Total	609	12	1	2	—

Results of Present Study

Preliminary Survey.—To ascertain the scope of this problem in Rochester, Minnesota, and the surrounding regions, an initial survey was made of the dairy products used by a single restaurant. These were pasteurized commercial products supplied by a large local dairy, whose field of distribution is both local and national.

Twelve of nineteen samples (63 per cent) of pasteurized whole milk, skim milk, buttermilk, cream and dressed cottage cheese tested on different days contained penicillin, identified by the use of penicillinase. Three of five specimens tested on another day contained an antibiotic other than penicillin.

Multiple checks on dry powdered milk, evaporated milk, dry cottage cheese, butter and ice cream showed that these products were consistently free of demonstrable penicillin or other antibiotics.

This initial survey, conducted in the spring of 1959, also showed penicillin to be present in the raw milk from two of five farms supplying the dairy; one sample contained 0.07 unit per milliliter.

Detailed Survey.—A detailed survey then was made of specimens of milk from the bulk tanks of 609 dairy farms, spread over a radius of 150 miles, that provided the source of milk for two large dairies. Two per cent of these specimens contained penicillin varying in amount from 0.011 to 0.07 unit per milliliter (Table I).

The discrepancy between this figure of 2 per cent, which was obtained in midsummer, and the previous incidence in the spring survey of penicillin occurring in two of the five farms and in 63 per cent of distributed milk products may be related to dilution and blending factors, as well as to seasonal variation in the incidence of mastitis in dairy herds. Bovine mastitis is commonest in the spring, when cattle are crowded together indoors while the weather is still cold and wet. This seasonal variation in mastitis and the related increased use of penicillin in spring may account for a seasonal incidence of reaction in consumers of dairy products. Thus, recurrent urticaria or other cutaneous reactions with exacerbations in the spring may be related to widespread use of penicillin for bovine mastitis at such times.

The manner in which penicillin in the milk from one farm can appear in a lower concentration in a larger volume was clearly illustrated when the milk from one farm, supplying 3432 pounds of milk in each bulk tank, collected every other day, showed the presence of penicillin in a concentration of 0.07 unit per milliliter. The milk in the tank of the collecting truck, containing 11,129 pounds of milk from this and several other farms, contained 0.018 unit per milliliter. Milk from the other farms did not contain any penicillin. The concentrations of penicillin measured in the bulk tank at the original farm and in the collecting tanker correspond to the dilution factor within 20 per cent. This shows that the laboratory estimations were accurate at least to this degree.

Comment

Sources of Penicillin.—In tracing the origin of this penicillin, it should be realized that approximately 25 per cent of the 26,000,000 cows in the United States have mastitis,[10,11] the incidence having increased with the widespread use of milking machines. Most of these machines will continue to "dry milk" the udder after the milk ceases to flow. This trauma predisposes to infection by Streptococcus agalactiae, a penicillin-sensitive organism that is involved in more than

70 per cent of cases of bovine mastitis. This condition usually is treated by dairy farmers themselves, using easily procured antibiotic preparations. The most commonly used method is to insert penicillin directly into the affected quarter of the udder via the teat, using the nozzle of a prepared, manually compressible plastic container. The dose of penicillin in these preparations is limited to 100,000 units by order of the Federal Food and Drug Administration. A directive on each container states that the milk from the treated quarter should not be used for human consumption for seventy-two hours after treatment is given.

However, it is extremely difficult to enforce these directions and they are not closely followed. Doses of penicillin in excess of 100,000 units often are given locally. Other antibiotics, especially neomycin, bacitracin and streptomycin, are added to these preparations. Extremely large doses of penicillin also are given intramuscularly in the treatment of bovine mastitis. Penicillin given in this way may be concentrated in the milk.[12]

The concentration of penicillin in milk may be so high, even after pasteurization, that "starter" cultures of the Lactobacillus used for the manufacture of cottage cheese may be inhibited.[13] This is of significant economic concern to the manufacturing dairies, who not only lose their product and time but also have considerable expense in disposing of the waste.

Suggestions for Control of the Problem.—The following suggestions may be advanced to minimize the contamination of dairy products with penicillin:

1. Improvement of herd management on dairy farms to lessen bovine mastitis, with avoidance of cold, wet and overcrowded conditions, especially when cattle are kept indoors.
2. Use of improved milking machines that automatically stop milking each quarter of the udder as the milk ceases to flow, avoiding trauma from "dry milking," which predisposes to the development of mastitis.
3. Use of antibiotics only under the supervision of veterinarians.
4. Education of dairy farmers to eliminate milk from treated cows from their bulk tanks.
5. Administration of penicillin to cows only when clear-cut indications for its use are present.
6. Close control by dairies, which can test milk for penicillin using the method already outlined. Such control now has been instituted by the large dairies in Rochester, Minnesota. They have outlined their program and its significance to their suppliers, and they reject all milk from any farm whose collected milk contains penicillin.
7. Use of dry powdered milk, which does not contain penicillin.

Summary

Severe reactions to penicillin given therapeutically now constitute a major health hazard. Reactions of sensitization may be expected to occur from the ingestion of milk and other dairy products containing penicillin used in the treatment of bovine mastitis. Urticaria that is recurrent or seasonal may be related to the variations of mastitis in cows, with peaks of incidence in the spring and fall. A local survey demonstrated penicillin in more than half of distributed pasteurized dairy products. Another survey showed penicillin in 2 per cent of the milk tanks on 609 farms. Methods of control are outlined.

Beliefs and Misbeliefs in Proctology

The author believes proctologists would do well to review their ideas and their practices regarding the common diseases of the anus and rectum. Unnecessary hemorrhoid surgery is frowned upon, and the author points up the need for a conservative approach to this problem. After reading this article, it is obvious the anal and rectal area is the seat of considerable controversy regarding management of specific lesions.

EXPERIENCE has been called the end-result of the incorrect performance of an act a sufficient number of times until eventually the performer becomes an expert at doing it the wrong way. The same may be said of ideas. One may acquire a false concept of a certain situation, and even though it is incorrect, this idea may be nurtured until it becomes a fixed belief. The thoughts expressed in this paper are to an extent sufficiently unorthodox so as to risk being placed in the latter category; however, I believe that with a modicum of logic they are tenable.

In medical discussions, not infrequently we hear that this or that particular operation is being performed too often, for example, too many gastrectomies, hysterectomies, tonsillectomies, et cetera. The same accusation has been directed toward hemorrhoidectomies. With this I disagree. The trouble is not that they are being done too often, but that often they are being done to the wrong people.

There is hardly a known pathological condition easier to diagnose than hemorrhoids. All one needs is an anoscope and reasonably good vision. The distinction, however, between hemorrhoids *per se* and those which are giving symptoms is not so easy since the latter diagnosis requires a certain amount of cerebration which is always tiresome. Should I be accused of exaggeration, let me add that I have had patients who have had hemorrhoidectomies for the relief of symptoms caused by ulcerative colitis, proctitis, backache, carcinoma of the rectum, carcinophobia, proctalgia fugax, the levator syndrome, carcinoma of the cecum, and anal pruritus. Needless to say, the operation was not a signal success in any of these patients.

In a manner of speaking, hemorrhoids are a sort of normal abnormality because there are millions of people in this country who have them and who are quite comfortable and symptomless. But to add to the confusion, a new type of patient has appeared on the scene. This patient is the result of the widespread propaganda to aid in the prevention and cure of cancer. He may be the one whose

HAROLD HULLSIEK, M.D.
Saint Paul, Minnesota

Uncle Joe recently died of cancer in California, and now he begins to worry as to whether or not he has cancer. As with many people, his self-consciousness prevents him from simply telling the truth; in his case, that he has no rectal trouble, but is worried, and he trumps up a number of fake symptoms which he describes with earnest plausibility. Once assured that he does not have a cancer this person is usually satisfied, and may even admit that his symptoms did not amount to much. However, since most laymen know that untreated piles turn into cancer, at least a few are willing candidates for surgery. This, of course, makes two strikes in favor of the doctor.

Internal hemorrhoidal tissue occurs to a greater or lesser extent in everyone over the age of thirty or thirty-five. Most probably, if any proctologist were questioned as to the truth of this statement, unless he thought it was a leading question, he would agree. Who, then, should be operated upon or treated? First, any patient who regularly bleeds from piles (and only after an accurate determination that this is so); and secondly, any patient whose piles prolapse on bowel movement, or on lifting or straining. The patient, who has as his chief complaint backache, leg-pains, vague rectal or pelvic pain, pressure, constipation, or anal pruritus should be viewed with a jaundiced eye insofar as treatment of his hemorrhoids is concerned. If a surgeon has not operated upon a patient suffering from the ills just mentioned, he may be accused of being a stupid doctor, but at least he is not about to be asked questions he cannot answer when the patient stays the same or gets worse following his operation. It is my belief that the mere presence of piles is not sufficient indication for operation, and even when hemorrhoids do give symptoms, they are almost always purely local in character.

Every year several new operations are described for the surgical treatment of piles with insistence that meticulous attention be paid to the peculiarities of the author's pet technique. I doubt that there are twenty or thirty different ways of removing hemorrhoids, all correct. Nonetheless, the one thing all authors agree upon, is that every vestige of hemorrhoidal tissue must be removed. And this despite the above-mentioned fact that there are literally millions of persons with moderate to large internal hemorrhoids who are going about their daily business contentedly and symptomless. Insofar as complete removal is concerned, I have examined patients who had had hemorrhoidectomies done by competent proctologists who adhere to the sacred tenet of complete removal of hemorrhoidal tissue, and yet these patients have had a recurrence to the extent of daily bleeding. This is not an indictment of the operation; it is merely an indictment of the operator who is certain that complete removal always prevents recurrence. I believe that in the main most persons will be completely and permanently relieved of their symptoms by the removal of the three main hemorrhoidal groups. If it takes a person thirty years to develop piles, it seems likely that with 90 per cent of the tissue removed, it will take him at least an equal time to develop hemorrhoids which will again give him symptoms. The fact that patients occasionally have recurrences after either the injection or after surgical treatment is no reason for condemning either method. I know of no treatment that can be guar-

anteed 100 per cent except amputation. Once a leg is off, it is completely and permanently off, and there is no argument about it. If patients are selected with reasonable judgment, I believe, the result by either method will be satisfactory. There are many patients who cannot be treated successfully by injections, but when they can, the treatment is quantitative, and is not a question of all or nothing as is true of a hemorrhoidectomy.

Let us take, for example, a sixty-year-old man with moderately large internal piles. His bowel habits are satisfactory and he has no anal or rectal discomfort. Last week he began to have daily bleeding with his bowel-movements. He is no worse off, nor is he different from what he was the week before except that he was not bleeding then, and now he is. Let us assume that it has been definitely established that his bleeding is from his piles. Two weeks ago he did not know there was anything amiss, but now, if he consults a surgeon, who treats piles only surgically, he is told that an operation is necessary. It is all, or nothing. I believe that this patient can have a sufficient number of injections to control his bleeding and that neither he nor I need be concerned about his piles. If it is truly of paramount importance that all hemorrhoidal tissue be removed, I suggest that all physicians submit to operation since they, together with 90 per cent of all adults, have some piles.

Now a few words about anal fissure. The patient with this condition has so typical a story that one can often make a diagnosis without examination. Nonetheless, after examination and diagnosis, the next decision is what to do about it. The recently formed fissure with no attendant sentinel pile, with no hypertrophied anal papilla, and with little or no anal fibrosis will almost certainly get well without surgery. On the other hand, the deep, chronic fissure with a sentinel tag, anal fibrosis, and anal papilla will never heal without operation. When one is uncertain about the various gradations between these two extremes, there is no harm in trying conservative treatment for two or three weeks before advising surgery. By conservative treatment I do not mean silver nitrate, ointments, or suppositories, none of which have the slightest influence on the healing of a fissure. Silver nitrate merely adds insult to injury, while even anesthetic ointments have a minimal effect on deep-seated pain. Suppositories for the relief of anal discomfort might better be inserted in the ear, which is more conveniently accessible, and where they will do as much good. My remarks concerning suppositories will probably have no deterrent effect on those who prescribe them for all patients on whom a diagnosis has not been made.

A peri-anal abscess gives a history equal to that of an anal fissure, that is, constantly increasing pain unrelated to bowel movement, which usually drives the sufferer to seek medical aid at the end of three or four days. If an abscess is suspected, and it should be from the symptoms, it still may be one of the few instances in which the tenderness and swelling are not sufficiently marked to make one certain. The importance of immediate diagnosis lies in the fact that if an abscess is present it should be drained the same day, while if none is present, the delay in diagnosis is not important. In cases of uncertainty, the leukocyte count is the deciding factor. With an abscess, the count will be between 12,000 to 20,000. If the count is normal, no abscess is present. I believe that a peri-anal or peri-rectal abscess which is scheduled for morning surgery has been mistreated since, having been seen the day before, it should have been opened at that time. Opinions to the contrary may be found in the textbooks, but I believe there is no excuse for waiting for such an abscess to "point."

The fanfare during the last few years over the subject of rectal and colonic polyps has done a vast amount of good. But it has served to breed considerable confusion in the minds of many, as well as frightened an impressive number of laymen. In the first place, the term polyp is an unfortunate one since it has a purely morphologic connotation and gives no hint as to the histologic type of tumor. Unfortunately, however, the term is here to stay.

It is assumed that the so-called polyp is a pre-malignant lesion, and it probably is. One must say probably because we have no way of proving that all polyps become malignant, nor, if they do, how long it takes. When we speak of pre-malignant polyps, what we are actually talking about are adenomas. We are fairly certain of the malignant potentialities of adenomata. On the other hand, a lymphoid follicle in the submucosa, or a papillary excresence with a normal mucosal covering, while possibly polypoid in shape, is not pre-malignant.

In 1955, Wilson, Dole, and Brines reported the results of 20,847 proctoscopic examinations. The incidence of adenomatous polyps was 3.95 per cent, while at the University of Minnesota Cancer Detection Center the incidence of so-called polyps was 16 per cent. This explains why examination

of patients from the Center by Twin Cities proctologists fail to reveal polyps in at least 50 per cent of the cases.

Because of their adjacence to the anus, pilonidal cysts and sinuses are assumed to lie within the province of the proctologist. There are few surgeons who are not acquainted with the troublesome so-called recurrences following operations for these conditions. I say so-called recurrences because I doubt that the failure to heal properly is frequently a recurrence at all. Without considering the cause of this condition, the theories of which are certainly under revision at present, let us consider the surgical treatment. In all surgery, the failure to restore the patient to good health comes under one of several headings. In the case of new-growths, for instance, it may be an incomplete removal of the tumor; in a surgical repair such as that of a hernia, it may be a failure to remedy the defect; sometimes it is a failure to eradicate a source of infection, and finally in the face of a completely successful operation, the unsatisfactory result may be due solely to the surgery itself.

In the case of pilonidal cysts, the complete eradication of the cyst is usually not difficult, and I imagine that in most cases it is accomplished. The recurrences are probably not as often recurrences of the original lesion as simply the inability of the healing tissue to cope with an area which has a peculiar topography. Many times the very extensiveness of the operation in itself is a cause of failure.

Many operations have been devised for this troublesome condition, and some of them quite ingenious, even as my own, which although theoretically perfect, in reality is not much better than the others. The cyst or sinus is located in a more or less deep groove between the nates. The more extensive the operation and the more tissue removed, the deeper the groove and its defect. During or even after healing, the sitting position tends forcibly to widen the defect, for the lines of force act laterally and secondarily and tend to pull the tissues outward from their healed or healing bed at the bottom. I have seen a healed pilonidal wound with firm skin develop a collection of blood or serum and finally break through, and leave the patient with the same situation he had at the beginning: a draining sinus. I think it quite probable that the less extensive the operation, the more likelihood there is of satisfactory and permanent healing. This is substantiated by a rather impressive series in which the author reports almost no recurrences. He merely laid open all tracts and removed almost no tissue.

As to my views on pruritus ani, I should like to quote from the address of the chairman of the Section on Dermatology of the A.M.A., J. Walter Wilson:

"To the dermatologist there appears to be only one logical line of demarcation that needs to be considered, the mucocutaneous junction at the anus. It cannot be denied that from this point outward all that which is encountered upon the surface of the body is skin, subject to all the diseases to which the skin in general is susceptible, in addition to a few that are peculiar to this area. Thus, it seems to the dermatologist that a physician must of necessity know the greater portion of the science of dermatology, if he is to claim the experience expected of a specialist in assuming the care of an ailment external to the mucocutaneous junction. Yet, some proctologists consider a circular area perhaps up to a dozen inches in diameter centered about the anus to lie well within their field. Dermatologists highly respect the ability possessed by proctologists to deal with such conditions as carcinoma of the colon, fistula-in-ano, hemorrhoids, and prolapse which require much specialized training and experience. It can be said with confidence that none certified in dermatology attempts to treat such proctologic conditions. Realizing the importance of acquiring and maintaining skill in such valuable techniques, proctologists naturally devote all of their study time to them and are never found in attendance at skin clinics. Thus, they have no opportunity to learn to respect the difficulties of dermatology. As an example of the resulting lack of diagnostic ability, proctologic literature contains many discussions devoted to pruritus ani. It is obvious to the dermatologist that pruritus ani is not a disease and that it does not even deserve to be classed as a diagnosis, since it is only the translation into Latin of the symptom complained of by the patient. It is also obvious to the dermatologist that there can never be a single truly successful treatment for pruritus ani since there are altogether too many different causes that must be differentiated and specifically controlled. Proctologists treat many cases on the assumption that they are due to fungus infections, yet never bother to ascertain whether fungi are present. Dermatologists treat itching of the anal area only if there is a dermatosis present that matches the symptom; otherwise consultation with a proctologist is advised. This is also their procedure when such itching does not subside quickly and simultaneously with the clearing up of the dermatosis since they realize that a deep-rooted disease may easily have been the original cause of such a complaint. Dermatologists are firmly convinced that it would be better for such patients if proctologists would reciprocate by displaying a similar respect for dermatology."

And so do I.

Injuries to the Eye and Visual Apparatus Associated with Injury to the Head, Neck, and Chest

Here is a comprehensive and useful review of the many possible injuries to the eye and its associated structures.

MAN'S DEVELOPMENT of terrific speeds of travel on and above the earth's surface, his increasing use of ever more powerful industrial equipment, and his ingenious development of ways of race destruction by means of instruments of war have resulted in heightening the incidence of head, neck, and chest injuries to an extent unknown to previous generations. But the increasing skill developed in dealing with these injuries has achieved a survival rate which is permitting us to better realize their immediate and remote after-effects. Many of the findings and after-effects of head injury have profound ophthalmological significance. Besides the secondary involvement of the visual apparatus in head and general bodily injury, we frequently see direct injury to the eye and its adnexa. The eye is well protected anatomically by the brow, orbital rim, and lids, and by its situation in an elastic fat pad. It is also protected physiologically by lid reflexes and by reflex head turning. In spite of this protection, the incidence of injury to the eye is relatively high.

Direct Injury to the Eye and Adnexa

The effects of injuries to the eye are much more severe than similar trauma to other parts of the body because of the delicacy of ocular tissue, and because trauma, which would cause only temporary inconvenience elsewhere, can cause blindness here. Ocular injury is a social and economic hazard which results in great loss of human happiness, in economic inefficiency, and in monetary loss.

Injuries to the eye in automobile accidents fall into two general catagories: lacerations and contusions.

Lacerations

Lacerations of the Lids.—Lacerations of the lids are of importance because of the possibility of serious sequelae which may cause visual loss. Serious complications of lid lacerations may be disalignment of the cilia with trichiasis, entropion, ectropion, coloboma with exposure of the globe, ptosis, epiphora, and cosmetic defects.

Lacerations which run parallel to the lid margins have edges which fall together easily and heal nicely; while lacerations vertical to the lid margins usually gape widely, due to the pull of the orbicularis fibers. Careful suturing of the muscle prevents unnecessary scarring and deformity.

Careful and adequate treatment of lid lacerations is of extreme importance because in this way one may prevent most of the serious complications of lid lacerations and minimize those lid deformities which can not be prevented. Repair of lid lacerations should be performed as soon as the patient's general condition will permit. Bleeding is controlled and the wound is cleansed of all foreign matter. Some times foreign bodies can be palpated with the finger tip more easily than they can be

RICHARD C. HORNS, M.D.
Minneapolis, Minnesota

seen. The wound should be irrigated with warm saline and a minimal bridgement carried out. The extent of the wound should be determined and the lid structures identified. At the time the lid wound is examined, the globe should also be carefully examined for evidence of injury. If the tendon of the levator muscle has been cut, it should be carefully repaired with fine chromic catgut sutures. A good repair of the levator tendon or muscle will prevent or minimize a future ptosis problem. In lacerations of the upper lid, one should have the patient raise his lid to check the levator function before anesthesia is administered. If the medial or lateral canthal ligament is cut, it should be repaired.

In lacerations through the entire lid, the margins must be brought together with meticulous accuracy to prevent notching and deformity. The posterior margins, as well as the lash line, must be brought together accurately. The lid is sutured layer by layer with fine catgut in the tarsus and orbicularis muscle. The skin is sutured with fine silk.

If the wound is more extensive and involves considerable loss of tissue, protection of the eye becomes a primary consideration. A good step in the plastic repair can be made by bringing skin from another area to fill the defect and by lining this with reflected conjunctiva or grafted buccal mucosa. Further plastic repair can be performed later.

Laceration of a lacrimal canaliculus is an unfortunate type of injury because the discomfort of epiphora may result. The lower canaliculus must be functioning to prevent epiphora for the superior canaliculus alone is usually not enough to carry away all of the tears. Loss of the superior canaliculus alone does not produce epiphora. The lacerated canaliculus should be sutured over a probe or cannula which is left in place from two to three weeks.

Laceration of the Globe.—Laceration of the globe, no matter of what degree, represents a severe eye injury. Vision may be lost due to secondary infection or to direct injury to the structures of the eye. In all head injuries where there is local injury about the eye or where the patient's spectacle lenses have been broken on the face, one must examine the eye for a perforating injury.

Lacerations of the cornea may be accompanied by a prolapse of the iris and injury to the lens. The laceration may extend past the limbus into the sclera. An attempt should be made to save all injured eyes unless the damage to the eye is so extensive that no hope of vision is present and the danger of sympathetic ophthalmia does not warrant attempting to save a blind eye.

When the cornea is lacerated, the wound is repaired by cleansing the wound margins of foreign

material and excising any prolapsed iris. Lens pulp in the wound is removed. The iris within the eye is reposited to free the wound edges within the eye. The corneal wound is sutured edge to edge with fine silk sutures (6-0 or 7-0) and fine hand honed cutting needles. Enough sutures are placed in the wound to make a tight closure, and air is injected to reform the anterior chamber. Antibiotics are given in large doses and penicillin and streptomycin are usually injected subconjunctivally. The eye is inspected daily and the corneal sutures may be removed in from twelve to fifteen days.

Lacerations which extend into the sclera present a graver problem because of the frequent loss of vitreous.

Scleral lacerations may also be studied unless the injury is extremely large. In that case, it is frequently wise to eviscerate the sclera and place a gold, glass, or plastic implant within the sclera, thus providing the patient with an excellent stump for a prosthesis.

Concussion and Contusion of the Globe

Injuries to the globe due to blunt force are varied and are frequently of a serious nature. The wounding capacity of the impact is related to the kinetic energy involved. The kinetic energy of a moving body increases arithmetically with regard to its weight and geometrically in relation to its velocity. If two bodies are traveling at the same rate, but one body has twice the mass of the other, the kinetic energy of the one is twice that of the other. If they have the same mass, but one travels with twice the speed of the other, the one will have four times the kinetic energy of the other.

Injury to the Lens in Contusion of the Globe.—The lens is frequently traumatized in these blunt injuries. Apart from paresis and tearing of the iris, lenticular changes are the most common sequelae of injuries of this type.

There may be various degrees of dislocation of the lens. If the lens is luxated into the anterior chamber, the eye usually develops a secondary glaucoma and surgical treatment to remove the lens is indicated. Dislocation of the lens into the vitreous occurs twice as frequently as dislocation into the anterior chamber. The lens in the vitreous is better tolerated than in the anterior chamber but may result in iridocyclitis and a general deterioration of the eye. Injury to the suspension mechanism of the lens varies in degree, and usually the dislocated lens remains in the hyaloid fossa. The lens is tremulous as is the iris. In the case of a young person, the lens becomes more spherical, and the eye becomes myopic. If the lens is freed from its zonules only on one side, the lens may assume an irregular shape so that the eye develops myopic astigmatism. The lens may gradually sink lower in the eye due to gravity, and vitreous may herniate past the lens into the anterior chamber.

Lenticular opacities following a blunt blow on the eye are not uncommon and present a variety of biomicroscopic pictures with the slit lamp. In general, there are three types of lens opacity following this type of injury. The first type is a ring corresponding to the pupillary aperture composed of myriads of reddish-brown granules of pigment deposited flatly on the anterior lens capsule. The ring is typically 1 mm. in diameter and probably represents iris pigment pressed into the lens capsule in the manner of a rubber stamp. This is called a Vossius ring after the ophthalmologist who first described it. The second type of lens opacity is that of localized opacity due to subcapsular change. This may be disseminated subepithelial opacity, it may be film-like cobweb opacity, or it may be lamellar in appearance. Sometimes these lens changes, especially if mild, will clear during the first few days or weeks after the injury, but in other cases, they will go on to an atrophic condition of the lens or precipitate the development of pre-senile or senile changes. The third type of lens opacity from blunt trauma is diffuse cataractous lens change which is usually associated with a capsular tear. This usually progresses to a total lens opacity. Children will frequently show considerable absorbtion of the cataractous lens material if the rent in the capsule is fairly marked. The great majority of lens opacities from contusion requires no treatment because the opacities are not marked and remain stationary. When the opacity is dense, surgical removal of the lens may be indicated.

Injury to the Choroid and Retina in Contusion of the Globe.—The choroid and retina suffer various degrees of damage from contusion and vision is frequently damaged due to injury to these structures.

Hemorrhage into and detachment of the choroid are common injuries due to contusion and are followed by secondary atrophic changes in the

retina. Another type of choroidal lesion, which is commonly seen in severe contusions, is choroidal tear, either single or multiple. Serious retinal lesions consist of concussion edema of the retina (commotio retinae), concussion necrosis of the retina, traumatic macular cysts and holes, peripheral retinal atrophy, and retinal detachment. A careful ophthalmological examination should be made of these eyes to search for damage to the retina and choroid.

Hemorrhage in Contusion of the Globe.—Intraocular hemorrhage is commonly seen after a contusion to the eye. The hemorrhage may be limited to the anterior chamber, hyphemia, and may vary in degree. Primary hyphemia appears at the time of the accident with a blood level in the anterior chamber. Such hemorrhages usually absorb readily, but the picture may be complicated by a secondary hemorrhage which usually occurs on the third or fourth day following the injury. The secondary hemorrhage tends to be severe and is a serious complication. The eye may be severely damaged in marked hyphemia due to secondary glaucoma and by blood staining of the cornea. Such staining of the cornea results when the anterior chamber is filled with blood and there is an elevated intraocular pressure.

The treatment of hyphemia is bed rest, sedation, and binocular bandaging. In the initial stages, cold compresses give comfort and may help to control the bleeding, while subsequently hot compresses may be of benefit. Atropine should probably not be used. If the intraocular pressure rises, miotics may be used as well as carbonic anhydrase inhibiting drugs such as acetazolamide. Paracentesis of the anterior chamber may be indicated if it remains full of blood and if there is an intractable secondary glaucoma. In some cases, lavage of the anterior chamber may be indicated.

Hemorrhage into the vitreous tends to absorb slowly, and if the hemorrhage is massive, vision is seriously threatened because of a persistent vitreous turbidity.

Ophthalmological Findings in Head Injuries

Ophthalmological findings in head injuries are extremly common. In 610 cases of fracture of the skull, Blakeslee[1] found that 475 (about 78 per cent) manifested eye signs. Most of these ophthalmological findings clear up, but late ophthalmological sequelae are relatively common. In analyzing 500 cases of head injury Hooper[2] found ocular sequelae in fifty-eight.

Hemorrhage into Lids, Conjunctiva, and Orbit

The finding of ecchymosis of the lids (black eye), orbital hemorrhage, and conjunctival hemorrhage brings up the question of the origin of the bleeding. The main point in differential diagnosis is whether this bleeding is due to local lid trauma, orbital bleeding from an orbital fracture, or whether blood enters the orbit from a basal skull fracture. Local contusion of the lids produces an almost instantaneous swelling of the lids due to edema and hemorrhage. This is frequently so marked that it may be extremely difficult or even impossible to separate the lids enough to examine the eye. The area of ecchymosis and edema extends beyond the orbital rim onto the cheek and forehead, and is not sharply circumscribed. The lids are typically reddish-purple following the injury with bright red blood seen beneath or in the conjunctiva. The color of the lids then changes in a few days through purple, greenish brown, and eventually to a yellowish appearance. In the vast majority of injuries to the local tissues about the eye, there is no serious eye injury but contusion to the globe may occur.

Hemorrhage into the orbit and lids from a fracture of the orbit or skull appears twelve to twenty-four or more hours after the injury. Usually there is enough bleeding in orbital fractures so that a fairly marked exophthalmos occurs. Sometimes the orbital bleeding will have localizing value as to the location of the orbital fracture. From a fracture of the roof of the orbit, the blood usually follows along the levator muscle and appears in the upper lid. From an apex fracture, the blood follows the lateral rectus muscle and appears under the conjunctiva temporally. From a fracture of the orbital plate of the sphenoid, the blood tends to follow the lateral wall of the orbit. In a fracture of the floor of the orbit, the blood appears in the lower lid.

Hemorrhage into the orbit from a basal skull fracture presents a similar picture to that of orbital fracture but may be somewhat more delayed in appearing. In basal skull fracture, the blood seeps along the floor of the orbit and appears typically toward the nasal side in the subconjunctival tissues of the lower lid. In Blakeslee's[1] series of 610 cases of skull fracture, he found subconjuncti-

val and lid hemorrhage in about 17 per cent of the cases. An extravasation of blood appearing in the orbit at an interval greater than twenty-four hours after a head injury with or without loss of consciousness is pathognomonic of fracture of the base of the skull.

Subconjunctival hemorrhage due to local injury usually has the dense part of the hemorrhage on the anterior portion of the globe and the hemorrhage thins out or disappears toward the equator of the globe. If the bleeding is retrobulbar in origin, the subconjunctival hemorrhage is most dense posteriorly and fades out toward the limbus. The hemorrhage may be conjunctival in cases of local injury while the hemorrhage due to posterior bleeding is subconjunctival, which can be demonstrated by moving the conjunctiva over the hemorrhage.

Hemorrhage into the lids from posterior bleeding tends to be limited by the orbital margins and the result is a circumscribed circular area of ecchymosis, whereas hemorrhage from local trauma usually extends over a wider area. This circular limitation in posterior bleeding is due to the attachment of the palpebral fascia to the orbital margins.

Pupillary Phenomena in Head Injury

Pupillary changes are common in severe head injury and occur in about two-thirds of all cases of basal skull fracture. Pupillary changes frequently disappear after a few days. Usually the pupillary changes are present immediately after the head injury. In some cases, pupillary signs may be late in developing. Mydriatics should not be used and, if possible, morphine should be withheld because of the danger of masking these pupillary signs.

Widely dilated pupils, fixed to light (Hutchinson's pupil), are seen in deeply comatose patients. This is a grave prognostic sign, for most of these patients die. In Blakeslee's[1] series, 95 per cent of these cases failed to survive. If the pupils are widely dilated but react to light, the prognosis is much better and only about 30 per cent of these patients die.

Unilateral dilation of the pupil with loss of both direct and consensual light reflex is an important sign in head injury. Uusually, a dilated fixed pupil immediately after the injury indicates an injury to the third nerve or the third nerve nucleus. In this case, there will be other evidence of third nerve injury such as ptosis and extraocular muscle palsy. If the dilated fixed pupil becomes manifest sometime after the injury, the finding is almost diagnostic of a subdural or extradural hemorrhage and there is usually a skull fracture present. The pupillary dilation may follow an interval of miosis. This finding is an indication for a decompression operation because it is due to a gross cerebral shift causing the hippocampus to herniate into the tentorial hiatus so as to impinge upon and stretch the third nerve. In a very high percentage of cases, the hemorrhage is on the same side as the dilated pupil and the pupillary sign is an indication as to which side the decompression should be done on. If the clinical finding changes gradually from a unilateral dilated fixed pupil to bilateral dilated fixed pupils, there is an increased intracranial pressure. Along with the pupillary changes, the patient will be found to have developed papilledema. Because of the importance of these pupillary signs and because these are sometimes transitory they should not be masked by the use of mydiatics or morphine.

Slight inequality of the pupils with sluggish pupillary reaction is a common finding in midbrain damage and is a more frequent sign of persistent damage to this region than ophthalmoplegia. The large pupil is usually the abnormal one.

Injuries to the Visual Pathways

The optic nerve may be injured directly by penetration of the orbit by objects or indirectly by concussion and fracture. Injury to the optic nerve is relatively common in concussion injuries, particularly those caused by a frontal blow and only occasionally when the injury is caused by a temporal blow. Optic nerve injury occurs rarely when the violence comes from the posterior direction.

Traumatic amblyopia and optic atrophy following a blow on the forehead is a condition which has been recognized from the time of the early writings in medicine and has received much attention through the years. Hippocrates interpreted this as a reflex amblyopia. Typically, the patient receives an injury from the impingement of a blunt force in the region of the forehead or brow. Upon regaining consciousness, the patient notices a complete loss of vision, usually in one eye, although

bilateral visual loss does occur. Not all of these injuries are associated with loss of consciousness, and there are cases on record where a relatively mild blow has caused complete optic atrophy. In a case of my own, an eighty-three-year-old woman in an auto accident hit her forehead on the back of the front seat of the car. She was never unconscious and her only severe injury was to the right orbit. She had no light perception in the right eye and no direct pupillary reaction. The pupil reacted consensually. She had exophthalmos with bleeding into the orbit. She developed optic atrophy and had no return of light perception. Skull x-rays were negative. Special x-ray studies of the right orbit showed a fracture in the region of the apex.

Many of these cases develop a complete loss of vision with optic atrophy, but other cases show varying degrees of recovery of vision. In some cases, the patient recovers completely. When vision returns, improvement usually starts about the third or fourth day and continues through a four- or five-week period. All degrees of visual impairment may occur and various sector and scatomata field defects may remain. In about 40 per cent of these cases, no light perception returns. Ophthalmoscopically, these eyes are normal immediately after the injury. Optic atrophy can usually be detected in from fourteen to twenty-one days, but it has been noted to appear earlier than this as well as later. There is probably a direct relationship between the distance behind the globe that the optic nerve is injured and the time it takes for optic atrophy to appear.

The mechanism by which the optic nerve is damaged varies in different cases. The optic nerve damage is probably due, in the majority of cases, to either fracture of the optic canal, subvaginal hemorrhage with pressure on or tearing of the nutrient vessels of the optic nerve, intraneural hemorrhage, or concussion of the optic nerve.

There are also chiasmal and post chiasmal injuries to the visual pathways. In many of these good recovery of vision occurs, but in some there is a permanent visual field defect. Most cases, in which there is severe injury to the optic tracts, have such severe brain damage that the patient does not survive. With traumatic lesions of the optic radiations, there are varying degrees of hemianopic field defect. There is a direct relationship between how far back along the optic radiations the injury is located and the similarity or congruity of the visual field defect in the two eyes. Frequently, there is considerable clearing of the field defect as the acute disturbance of the trauma subsides. Trauma to the frontal and occipital region, particularly by a blunt force, may produce occipital lobe injury. The visual field defect is usually transient but occasionally small homonymous scatomata appear which are permanent. These injuries are frequently on the basis of a contrecoup mechanism.

Ocular Motor Phenomena

Ocular motor injuries complicate about 1 per cent of all head injuries.[3] The clinical picture varies from total ophthalmoplegia to syndromes involving individual nerves. The nerves affected are the sixth, third, and fourth in order of frequency. When the third nerve is injured, there is an accompanying ptosis. Complete third nerve involvement occurs infrequently, and one must suspect a fracture through the superior orbital fissure. In this case, there is also anesthesia of the cornea due to damage to the first division of the fifth nerve. Often with these severe orbital injuries, also optic nerve damage occurs. The site of the injury may be nuclear or a nerve root lesion due to brain stem trauma. There may be trunk lesions due to basal fracture, or mechanical displacement of the nerves caused by a meningeal hemorrhage.

When paralysis immediately follows the injury, there has usually been a direct injury to the nerve; while in cases where the paralysis is delayed, the paralysis is a result of pressure usually due to bleeding. The prognosis for return of function is much better in the delayed paralysis. Prognosis for recovery from all types of extraocular paresis is surprisingly good, although three to nine months may elapse before diplopia disappears. With residual paresis, diplopia may be overcome by prisms; but if the diplopia is so marked that prisms will not help, surgery on the extraocular muscles is indicated. During the recovery period, there is a great tendency for the patient to occlude or not use the eye with the paretic muscle. He should be prevented from doing this because he may promote the development of contracture of the direct antagonist to the paretic muscle thus making the return of function even more difficult. The patient should use one eye one day and the other eye the next day in a program of alternate occlusion and thus minimize the tendency for secondary con-

tracture. Ample time for natural recovery should be allowed before surgical correction is considered and before compensation claims are satisfied. Many cases require from nine to twelve months to reach a stable point.

Ophthalmological Findings in Injuries to the Neck and Chest, and to the Sympathetic Chain

Interruption of the sympathetic chain in the neck produces Horner's syndrome, first described by Claude Bernard and by Horner in 1869. This syndrome consists of miosis, narrowing of the palpebral fissure, enophthalmos, and ocular hypotony on the side of the neck injury. There is also loss of sweating and increased skin temperature on the same side of the face. Horner's syndrome is often incomplete. The miotic pupil reacts normally to light and accommodation. The pupil usually fails to dilate with cocaine which serves to differentiate it from a spastic miosis. If adrenalin is then placed in the eyes, the pupil on the affected side dilates more widely than the pupil of the normal eye.

Traumatic Retinopathy of Purtscher

It has long been known that following severe bodily injury, especially crushing chest injuries, a change occurs in the fundus of one or both eyes. This change consists of fluffy whitish-grey opacities in the retina which resemble exudates. These are associated closely with the retinal vessels and are frequently numerous in the macular area, but may be extensive and involve much of the fundus. They lie along retinal vessels, and the vessels may be hidden by them. They are usually associated with retinal or sub-hyaloid hemorrhages. The hemorrhages may be extensive and resemble those of retinal vein thrombosis. These findings usually appear from two to four days following a severe crushing injury.

There have been various theories as to the causation of the retinal lesions. Purtscher thought they were due to a rush of cerebrospinal fluid forced from the subarachnoid space through the disc along the paravascular sheaths of the retinal vessels. Other theories have to do with vascular spasm, increased venous pressure, and increased vessel permeability due to small rents in vessel walls as a result of concussion changes.

The actual mechanism of these retinal changes is probably varied and more than one factor may be operative. At the present time, it seems quite likely that in many of these cases fat embolisms play a role. Fat emboli have been found abundantly in the small vessels of the retina, optic nerve, and uveal tract in eyes with retinopathy of Purtscher.

Many of these patients die from the fat embolism or other features of their bodily injury. In surviving patients, the retinal lesions begin to fade away after four to six weeks and there are varying degrees of retinal deterioration which remain. In some cases, there is also optic atrophy.

Compression Cyanosis

In some crushing injuries of the chest or abdomen where there is a marked compression, as may occur when the body is pinned down by a heavy weight, a marked engorgement of the veins in the head, neck, and upper thorax, occurs. There is a dusky purple cyanosis of the head, neck, and upper chest, and sometimes of the upper arms. Edema is present and there are intra-cutaneous petechial hemorrhages. There is frequently proptosis due to orbital bleeding. Ophthalmoscopic examination shows a marked engorgement of the retinal veins with edema of the retina and many large retinal hemorrhages. Occasionally, blood is found in the anterior chamber of the eye due to rupture of some of the engorged vessels. Vision becomes poor because of the disturbance of the retinal circulation. The development of papilledema with severe loss of vision suggests the occurrence of bleeding into the optic nerve. An important factor in the production of this clinical picture is the absence of valves in the large veins above the heart. Some cases which have been called Purtscher's disease may have been compression cyanosis without the cutaneous manifestations.

From the ophthalmological point of view there is little to offer in the way of treatment unless emergencies arise such as secondary glaucoma from anterior chamber hemorrhage or corneal exposure due to exophthalmos secondary to orbital hemorrhage.

Normal 61 per cent	121	4	2	1		2

Read at the annual meeting of the Canadian Association of Radiologists, Toronto, Ontario, January 24-27, 1960.

SUFFICIENT information undoubtedly exists to confirm the dependability and accuracy of the radiologic diagnosis of diseases of the gall bladder. Several studies show this accuracy to be well over 95 per cent.[1,2] Statistically, then, the radiologist has developed a firm sense of security when rendering cholecystographic diagnoses. Consequently, in many cases, we have tended to allow the routine cholecystographic study to become a casual matter and because of this attitude may overlook lesions and perhaps do not give the patient the whole benefit of the procedures available. As radiologist in a small general hospital one is occasionally challenged by a colleague who is unwilling to accept a negative report in a given patient and at times even a positive report may be looked upon by him with some doubt. Stimulated, in part, by these occasions, it was thought advisable to review an unselected series of our cases to obtain at least a gross concept of the results and reliability of our methods of study. At the same time the methods of study could be reviewed, perhaps thereby providing better guides for our clinicians in the handling of their patients.

Methods of Study—Our methods of x-ray study of the gall bladder are based on simple routine procedures commonly used in all hospitals and offices. The patient is given the oral tablets in the evening after a light fat free meal and is brought to the x-ray department twelve to fifteen hours later. The material we have favored using over the past several years is Telepaque.[3,4] Ideally a plain predye 14 x 17 scout film of the abdomen should be made as a routine but as yet this has not been adopted into our routine.[5,6] Such a film is of considerable importance and on it one may often detect gall-bladder calculi, a calcified gall bladder, air in the biliary ducts or other abdominal lesions. When the patient reaches the x-ray department a scout film of right upper quadrant is made. If the gall bladder is not seen on this film, a full 14 x 17 abdominal film is made. This serves the purpose of locating the gall bladder in an unusual position; unabsorbed contrast material may confirm it was actually administered and retained; other unsuspected diseases outside the biliary system may be disclosed.

If calculi are seen on the scout film, the examination is discontinued. If one calculus is seen, a second film, probably in the decubitus position is made to see if the shadow changes position inside the gall bladder and thus make it possible to exclude a polyp.

Once the gall bladder is located, the detail studies follow. These include two oblique views and a decubitus view. This decubitus view is the most important of all the views.[7,8] It can be done with the existing equipment of most x-ray departments. The film is made with the patient lying on the right side with the x-ray beam passing horizontally through the gall-bladder area. The patient may be placed on a stretcher lying on his right side and the film made using the bucky of the upright x-ray table. This position will allow separation of the gall bladder from gas in the bowel, and many times calculi will be visualized which could not be seen on any other film. The erect study is rarely done as it is considerably less satisfactory than the decubitus view. A film after a fat meal is usually

done, not because we are interested in whether the gall bladder contracts, but because occasionally detection of small stones in the smaller volume of contrast material that is present after the contraction may be possible.

If the gall bladder does not function on the first attempt, we make sure that the patient had carried out the instructions, that the material can be and was absorbed, that it can reach the gall bladder, and then we repeat the examination usually the next day, but occasionally with a time interval. Analysis of our material reveals that only a few gall bladders that do not visualize on the first day, do so on the second. We still do "repeat" cholecystograms but we are not as insistent on them as we once were and occasionally will go ahead with other procedures rather than make the patient spend an extra day in the hospital.[9]

At the time these roentgen studies were made, we were not using pre-examination fatty meal or planography and we did not do any fluoroscopy or spot films of the gall bladder. We occasionally used a fatty meal at noon the day preceding the examination to empty the gall bladder. This allows one to be more confident that the gall bladder has space available to receive the dye.[10]

Another method we have used is the four-day Telepaque test. Some gallstones become visible by precipitation of contrast material on their surfaces after prolonged exposure to the contrast material.[11,12] This is true, particularly, in the case of biliverdin pigment stones. According to Salzman, this is a good method of identifying gallstones, and also bile duct stones "which will opacify in over 75 per cent of cases." To produce this prolonged exposure to contrast material, the patient is given one gram of Telepaque q.i.d. for four days. Following this films are made following the regular routine.

The gall bladder may also be examined by the use of intravenous contrast material.[13] The examination is carried out as for intravenous cholangiogram. The dye is concentrated by the liver and fills the gall-bladder through the cystic duct. This occurs as long as the cystic duct is patent. One can then evaluate the size and shape of the gall bladder and its contents. This test gives no information as to gall-bladder function but is valuable in confirming the presence of stones or of cystic duct obstruction. This intravenous method is valuable in the differential diagnosis of acute cholecystitis.[14] It is frequently difficult to differentiate between acute cholecystitis and acute pancreatitis and this is often an important clinical problem. Symptomatology and clinical findings may be indistinguishable and frequently both have a history of previous colic. Keeping in mind the commonly accepted pathogenesis of acute cholecystitis, that is, cystic duct obstruction, one should be able to opacify the gall bladder in the patient with acute pancreatitis, while in the patient with acute cholecystitis the gall bladder cannot fill because of the obstructed cystic duct. Therefore, if an intravenous cholangiogram is done, and this can be done independent of gastric intolerance or faulty absorption and in fairly short interval of time, the presence or absence of gall-bladder filling would assist one in making the differentiation.

Other methods of evaluating the gall bladder in cases of possible acute cholecystitis are based in the main upon the history of previous studies, which may have shown calculi or non-function with a double dose of oral contrast; or, in the case of patients who have had no previous studies, or have been normal previously, a plain film of the abdomen may occasionally be helpful as well as the intravenous dye studies.

Criteria Necessary for a Normal Gall-bladder Report.—

1. Concentration of the dye to any degree is considered normal.[15,16] Since only a small amount of functioning mucosa is necessary for concentration of the dye, some cases of cholecystitis do concentrate the dye and when calculi are not present would be interpreted as normal. This is the type of patient that raises the most discussion with the clinician. Final diagnosis depends on correlation with other clinical findings. However as long as there is concentration of the contrast with no other abnormal findings, we continue to interpret these gall bladders as normal.

2. No calculi or polyp shadows within the gall bladder.

3. No Rokitansky-Aschoff sinuses.[17] These consist of projections of the contrast shadow beyond the smoothly outlined wall of the gall bladder producing a somewhat irregular pattern. They are taken to indicate partial or intermittent obstruction of the cystic duct with subsequent back pressure.

4. No calcification in the gall-bladder wall. This of course may not be seen in a gall bladder that functions unless one takes a pre-dye scout film of the gall-bladder area.

5. The gall bladder may lie in any position, be of any size and configuration and still be normal.

6. Contraction or non-contraction of the gall bladder after a fatty meal is of no clinical significance.

Review of Cases. — The records of 200 consecutive patients who had had routine cholecystographic studies in our hospital beginning in January, 1954, were reviewed as to the x-ray diagnosis. In the spring of 1959, the hospital records of these patients were then reviewed to obtain information as to the medical course, subsequent admissions and pathologic correlation. Thus there was a time interval of from four to five years between the x-ray studies and the follow-up study.

Study of the 200 x-ray reports revealed that abnormalities were reported in seventy-nine cases (39 per cent). The gall bladder was visualized with calculi in thirty-six. In several where calculi were faint or very small, persistence in examination with the use of different positions and techniques had resulted in the correct diagnosis. This persistence was usually stimulated in me by the clinician who would refuse to accept a normal report. Twenty-four of these patients have been operated upon and all showed cholecystitis and cholelithiasis. This operative rate of two-thirds may seem low, but we live in a conservative community, and furthermore, many of the patients were aged.

In twelve cases, there was non-visualization with calculi; ten of these had surgery and all showed the expected pathological findings. In thirty-one cases there was non-visualization without opaque calculi. Twenty-one of these thirty-one patients were operated on and all showed pathologic lesions. There was one case of carcinoma of the gall bladder with stones, one of carcinoma of the common duct, sixteen with calculi and cholecystitis, three with cholecystitis alone.

Of greater interest are the 121 cases which were interpreted as having normal function without calculi. Four of these patients were operated upon with the pre-operative clinical diagnosis of cholecystitis. Two were found to be normal by the pathologist. However, only one of these had subsequent hospital admissions for abdominal trouble, the other patient being apparently cured. The third patient received a pathological report of "mild cholecystitis, no calculi." This patient has been in the hospital on three subsequent occasions with varying diagnoses such as functional dyspepsia and gastritis. The gastrointestinal findings are normal. The fourth patient is interesting in that the roentgen report was "normal function without calculi. The irregular and unusual shape of the gall bladder raises the suspicion of surrounding adhesions." The operating surgeon reported several adhesions and a small stone in the cystic duct. The pathological report was "the gall bladder is 9 cm. long, moderately thickened, and shows some yellow foci in the mucosa. Microscopic sections show cholesterosis and mild chronic cholecystitis."

Therefore, as far as the abnormal cholecystograms were concerned, no error in interpretation was found; most, but not all, were pathologically confirmed. There were two errors discovered in the 121 gall bladders interpreted as normal. Since only four of the 121 patients were operated upon, there is no way to confirm our normal findings in the other 117. However, several of these patients were found to have lesions elsewhere in the gastro-intestinal or genito-urinary tracts and were treated for these. Very few of the remainder, who had been found normal on other studies, have returned to the hospital in the interim.

The results of this review are consistent with other more comprehensive reviews that have appeared in the literature. It serves to confirm our faith in our methods of gall-bladder examination and in the criteria used in our interpretations. During the review of these cases, it was noted that several patients who had symptoms strongly suggesting gall-bladder disease, but with normal cholecystogram findings, turned out to have other serious lesions. On the other hand, in the presence of gall-bladder disease, serious lesions often coexisted. One must never develop a blindness to other lesions when calculi or nonfunction is seen, or persist in considering a faint shadow abnormal and not pursue other possibilities.

Intravenous Cholangiography

Evaluation of our x-ray studies of the bile ducts by means of intravenous cholangiography has not been nearly as satisfactory. Our intravenous cholangiogram is performed by the usual methods using Cholegrafin.

Criteria of Diagnosis.—

1. The size of the duct:[18] There are many reports in the literature which indicate that there is

a wide range in size. In large series of cases, the size of the unobstructed duct varies from three to 15 millimeters, whereas the diameter of the obstructed duct ranges from 8 to 30 millimeters. The range in size from 8 to 15 millimeters is one of considerable overlap. Since 50 to 60 per cent of visualized ducts will fall into this group, it is apparent that the size of the duct will not allow a distinction as to the presence of obstruction.

2. The duration of opacification:[19] To determine the duration of opacification, films are made at one and two hours. In the unobstructed duct the opacification is usually densest at one hour and then gradually fades. It is possible therefore to make a diagnosis of partial obstruction on this basis; that the density of the dye does not decrease in two hours from its maximum at one hour.

3. Filling defect: These are most difficult to detect due to overlying shadows and may require several projections.

4. Cystic duct remnant.

A review of fifty-two consecutive intravenous cholangiograms examined in 1957 and 1958 reveals that approximately 36 per cent of the examinations had such faint concentration of the dye that little if any information of value could be obtained. Of these fifty-two patients, forty-one had had a previous cholecystectomy. Of these forty-one, 46 per cent had visualization too faint to be of diagnostic value. Of course, in several of these the presence of clinical jaundice almost precluded the expectation of a good examination,[20] but since it was precisely in the jaundiced patient that one had most need of more information, the examination was attempted because occasionally helpful findings will be obtained. Also at that time we did not have laminography available. We hope to improve our results in the future with its use.

In about 19 per cent of the cases there was good enough concentration of the dye to evaluate two of our criteria; these were the size of the common duct, and whether or not the opacification persisted. However, in these cases it was difficult to exclude the possibility of filling defects or even of a possible cystic duct remnant.

In the remaining 34 per cent, concentration of the dye and separation from overlying shadows was such that definite diagnoses could be made with all four of the criteria fulfilled. Either the findings could be said to be normal or a definite abnormality was seen. Most of these patients were not jaundiced. The main complaint was usually vague post-cholecystectomy pain. Most of these patients were considered to show normal findings; none of these was explored but were managed medically.

In the abnormal cases, two cystic duct remnants were found; there was one case of common duct calculi and two cases of possible partial obstruction due to stricture but these last two are not proved. The intravenous cholangiogram did not often help us demonstrate stricture or other forms of obstruction because nearly all cases had appreciable jaundice and the ducts did not visualize.

I have been somewhat discouraged with what seems to be a low yield from our intravenous cholangiogram studies. However, since our colleagues still ask for this examination, they must feel that some value is being obtained. In our hospital, as in the larger reported series, the test is of most value in the post-cholecystectomy patient with pain or discomfort without jaundice.[21] In the obstructed cases, the value decreases considerably. Our visualization rate of 54 per cent compares poorly with the reported rates of 80 to 85 per cent. Since this visualization rate will depend on the selection of cases, that is, as the degree of liver damage increases, the rate of visualization will decrease, perhaps we have selected too many jaundiced patients. Also our results could probably be improved with body section studies which we will use in the future.

Summary

1. Our present methods of gall-bladder study and diagnostic criteria appear adequate.

2. Other serious diseases may mimic gall-bladder disease and may co-exist with gall-bladder disease.

3. Routine oral gall-bladder study deserves just as much individualization as any other examination. Consultation between clinician and radiologist is always of value and should be carried out in any questionable case.

4. Diagnosis and differential diagnosis of acute cholecystitis may be expedited by knowledge of previous roentgen studies, by plain film studies and by intravenous cholangiography.

5. Our bile-duct study yields could be improved by the use of improved techniques and by the more careful selection of patients.

Roentgen Diagnosis of Paranasal Sinuses

Presented at the meeting of the Minnesota Radiological Society, November, 1959.

SÖLVE WELIN
Malmö, Sweden

From the Roentgendiagnostic Department of the University of Lund (Head: Professor Sölve Welin), Malmö allmänna Sjukhus, Malmö, Sweden.

SINCE RECENT years have witnessed hardly any noteworthy strides in this field, and since I have no new tricks to show, there remains but one thing for me to do, and that is to give an account of how we usually perform the examination in Sweden, or to be precise, how we do it in the department of diagnostic radiology at Malmö.

It appears rather strange that while diagnostic radiology has been marching ahead during the last few decades, the diagnosis of diseases of the sinuses has, so to say, been simply marking time. The only explanation I can find for this is that advances in other fields of medicine have not placed new demands on roentgenology of the sinuses and that, at least for the time being, we can give the surgeons the information they require.

At the international congress in Munich in July, 1959, at which 921 papers were read, only one dwelt on the sinuses. That lecture was given by an Italian who gave an account of his experience with tomographic examination of tumours of the sinuses.

Before I discuss the technique we use in Malmö let me first describe briefly how we feel about tomographic examination of the sinuses. In cases of malignant tumours or suspicion thereof, we have used tomography as a supplementary method, but later we stopped doing so because we found it seldom gave any information over and above what might be obtained by ordinary roentgenograms, that is, a thorough examination with films in various projections and of good quality. If the roentgenogram shows bone destruction, tomography will seldom add further information. In those cases in which we were doubtful whether the bony walls had been involved, tomography did not give definite information. This does not imply that tomography might not occasionally provide useful information. Particularly in the examination of patients with cerebrospinal rhinorrhea and those in whom transphenoidal hypophysectomy is contemplated. Personally, however, I should never dare to replace ordinary routine examination by tomography, at least not in the investigation of clinically suspected cancer.

Owing to the complicated anatomy of the nasal region, examination of the sinuses requires films in several different projections. In the choice of projections, we try to find an optimal projection for a certain sinus and, at the same time, to judge the various sinuses on the basis of as many projections as possible. In addition, the projections should be such as can be readily duplicated on later check examination. We resort to the stereoscopic procedure in special cases, but not routinely. We use a Schönander skull table. In routine examinations, we usually take films at five angulations, of which at least two are taken with a horizontal beam. However, the information desired by the surgeon as well as the roentgenologic findings sometimes make it necessary to take further films at different angulations.

In the first projection, the patient is sitting upright with the forehead and the nose pressed firmly against the table which is angled at 30 degrees from the vertical plane and leans against the patient's forehead. The beam is directed horizontally and in this projection the radiograph offers a good means of studying the extension of the frontal sinuses in the coronal plane, their outline, and their division into partitions. Furthermore, it gives

good information on the basal parts of the frontal sinuses. We can also judge the ethmoids and the maxillary sinuses.

In the second projection the film is primarily intended to investigate the maxillary sinuses, and it is important that this exposure be taken with the mouth wide open and that the head is extended so far backwards that the tip of the petrous bone is projected below the floor of the maxillary sinus. This sometimes makes it necessary to increase the angle of extension by inserting a pad between the forehead and the table. The nose and the mouth are being pressed against the skull table, now angled 20 degrees from the vertical plane. In this projection, it is possible to see fluid levels in the sphenoid sinuses since they are projected through the open mouth. Proper, careful adjustment of the patients is necessary, especially if they are children. If the head is tilted or if the central ray is eccentric, or if the film is underexposed, the roentgenogram might give the erroneous impression of a density, especially of the maxillary sinuses.

Anatomic factors must also be borne in mind in the interpretation of a film. The relative thickness of the bony walls in relation to the size of the sinus cavity might severely impair the translucency of the maxillary sinus. It is obvious that alterations in the thickness and appearance of the vault bones as well as of the antral bones can to some extent influence the apparent translucency of the antrum.

On the ordinary lateral view, we can carefully examine the prevertebral soft tissue shadow. A pathologic broadening of this can be caused by a malignant tumour which is seen occasionally as an incidental finding upon examination of the paranasal sinuses. In recent years, this view has assumed special importance. In all cases of head injury and in particular in severe cases where the patient's condition will not permit removal from the stretcher, we supplement the examination of the head by a lateral view of the sinuses taken with the patient supine and with a horizontal beam. We have found that in fractures of the lamina cribrosa, fluid is sometimes demonstrable in the sphenoidal sinus, even in the absence of any detectable fracture line. This is caused either by blood or by cerebrospinal fluid, and we have one case in which we were obliged to take the films again after a few minutes and in which we could show that it was a question of a very profuse flow of fluid since the fluid level had risen considerably. It is true that we can only see this phenomenon in a small percentage of acute examinations. But when we did see a fluid level, it was of such importance that I thought it was worth while including such a film in routine examination of head injuries.

The standard projections include the conventional axial film. In this film, the ethmoids and the sphenoidal sinuses show up distinctly.

The increasing frequency of transsphenoidal hypophysectomy in advanced cancer mammae with skeletal metastases, has aroused interest in these sinuses. The sphenoidal sinus varies widely in its anatomy from one person to another, and especially in its relation to the sella turcica. The bony septum between the two sphenoidal sinuses is in the midline only in about one third of all persons. Anteriorly it usually runs sagitally, but further posteriorly it deviates in one direction or another. Sometimes it may terminate before the sella turcica, often at the bony canal surrounding the carotid siphon. The posterior margin of the septum does not coincide with the mid-line. This is important for the surgeon to know. In a few per cent there is also a transverse septum, which extends from the upper part of the anterior wall of the sella turcica down to the floor of the sinus. Such a transverse septum makes the work of the surgeon difficult because it masks the sella whose anterior wall is thickened and fastened to the septum. Sometimes the septum persists only as a flat rib on the anterior wall of the sella, and then it is called a crista transversalis. Sometimes only the medial part of the septum persists, and then it might be very difficult for the surgeon to orient himself.

It is obvious that a very thorough roentgen examination, sometimes with supplementary tomography, is desirable before transsphenoidal hypophysectomy, since such roentgen examination will facilitate the work of the surgeon considerably.

In ordinary roentgen examination of the nasal sinuses it is, however, particularly the frontal sinuses on which the clinicians want information because they are the most difficult to examine clinically. Unfortunately, these sinuses are also very difficult to evaluate roentgenologically. For appreciation of the frontal sinuses, we use a special projection, the so-called overshot axial projection. I have found that the reliability of the roentgen findings has in many cases been increased from the surgical point of view. In this projection the patient may be in a sitting or supine position with the beam directed submentovertically. The head is extended backwards so that the mandible is pro-

jected in front of the sinuses, and the beam runs along their posterior walls. In this projection the antero-posterior depth of the frontal sinuses can be clearly estimated both in their medial plane and their lateral extensions. Furthermore, the thickness of their walls can be evaluated, which is of great importance in the analysis of these pictures.

The varying degrees of translucency in the different parts of the frontal sinus in the postero-anterior projection may sometimes be so marked as to simulate a pathologic density and lead to an erroneous conclusion. This difference in translucency can at times depend on a different depth of the air volume in one sinus as compared with the other, and an abnormal bulge can give a similar difference in the same paranasal sinus.

We have also had cases where we might doubt whether there is any frontal sinus. These are the patients with pronounced unilateral osteosclerosis from an old inflammatory process with much bony proliferation. The bone structure may in the first standard projection be entirely homogeneous and almost as dense as normal compact bone. In such cases, through the use of the overshot axial picture, it is possible to determine whether the frontal sinuses are lacking or not. The view using the postero-anterior beam and the overshot axial picture are thus complementary and the projection is superior to the ordinary profile picture, when the depth of the frontal sinuses in their entirety is to be established. Despite the great improvement brought about by the introduction of the projection, cases are nevertheless still found in which radiology cannot with certainty establish, whether a frontal sinus is affected or not. Such cases are, however, fairly uncommon and they will obviously become still more uncommon with increased experience.

A density of the frontal sinus is sometimes seen with a rather distinct horizontal upper border in the basal part; it may be difficult to decide whether the change is due to the bone, a swelling of the mucous membrane, or a retention of secretions with fluid level. To arrive at a decision, we use the same projection as in the first frontal view, but the patient is now lying in true lateral position. This projection is, in our experience, of greater value than the oblique projection of other authors since it will reveal even the smallest amounts of fluid when other projections fail to do so.

The earliest sign of a pathologic process in a sinus is a thickening of the mucosal lining. Two main etiologic factors are responsible for this, allergy and infection. Both these factors may be present in any individual case and, although it may occasionally be possible to differentiate the allergic form from the infectious change, in many cases this is not possible. One usually says that a scalloped mucosal swelling, a marked degree of mucosal thickening, a polyp formation and hypertrophied and swollen turbinates suggest allergy. It should be remembered, however, that these signs only appear when sinus contains some air and in the completely opaque sinus it is not possible to differentiate these two states.

As far as the maxillary sinuses are concerned, it may sometimes be difficult to distinguish between polypoid thickening due to allergy and a large solitary polyp. In such cases, an examination in different projections and different directions of the beam may sometimes permit a differential diagnosis, a polyp being pedunculated while a non-secreting cyst is always sessile. But clinicians very seldom ask for a differential diagnosis, and we have therefore never found it necessary to fill the sinus with contrast medium. As a matter of fact, excepting operated cases in Sweden, we no longer use contrast injections in the examination of the nasal sinuses. Some years ago we still did so to differentiate malignant tumours, but since the method did not give really reliable information, we dropped it.

Signs of expansion and abnormal translucency are the two commonest roentgenologic signs of a mucocele, and there is usually no difficulty in establishing a positive diagnosis. Formerly, it was assumed that an increased density suggested the existence of a mucocele with sterile contents while increased translucency was a sign that it had been infected. But this does not fit in with our experience. Nor is it surprising since the increased translucency must be present in all cases where the bone walls have become thinner because of atrophy due to the presence of an expanding lesion. In other words, the density will not permit any conclusions as to the content of a mucocele. These processes are generally found in the frontal sinuses and ethmoids and they often look like rounded or oval cystic formations. However, they vary in shape, probably because of variation in the resistance offered by the bone. In some cases the pressure results in large bony defects.

Personally I am inclined to believe that the post-operative changes in the sinuses offer the greatest difficulties, especially where such patients are re-

ferred to us for suspected malignant neoplasm. We usually find a diffuse density with a greater or lesser operative defect, also usually a lack of definition in the surrounding contours. These changes are the result of operative and postoperative changes. It does not, however, permit any conclusions concerning the possible healing of the lesion. It does not provide any definite information concerning the possible presence of a soft tissue lesion.

In the case of frontal sinuses we cannot say anything concerning the patency of a recently constructed fronto-nasal passage. In such cases we may continue the investigation by the introduction of contrast medium into the nasal cavity, with regard to the roentgen diagnosis of the so-called secondary mucocele, arising in frontal sinuses previously subjected to radical operation. In the cases in which the fronto-nasal duct has remained open, the contrast medium runs directly up into the operatively treated frontal sinus. By examining the patient in different positions and always using a horizontal beam, it is possible to fill the different parts of the frontal sinus with contrast medium and to map the operative cavity. In the cases, where it is impossible to fill the frontal sinus with contrast medium through the fronto-nasal duct, the roentgen examination is continued with a direct puncture of the frontal sinus and injection of the contrast medium through the puncture needle. An ordinary needle puncture is obtained under local anesthesia into the medial angle of the orbit, approximately one centimetre from the midline and somewhat medial to the supra-orbital margin, at the site of the former trephine opening. A few millimetres of contrast medium is injected and if the frontal sinus is filled with soft tissue, a diffuse distribution of the contrast medium is obtained. If a mucocele is present, the picture varies according to whether the contrast medium is injected into or outside of the mucocele.

Finally, we come to the tumours, which is the most important field and I might just as well say now, that I do not know any particular trick to discover malignant neoplasms. The only thing we can do is to take films in a sufficient number of projections, to see that we get good film quality and to try to interpret the films as carefully as possible.

In addition to the standard projections I referred to just now, we always use one more projection, which we have found very useful, in the investigation of neoplasms. This film is taken with the patient prone with the chin and nose against the table and the tube angled towards the feet at 15 degrees. In this film the bony walls of the maxillary sinuses are very distinct and can be judged all the way round. The great wing of the sphenoid can also be examined, which is of great importance for diagnoses of malignant neoplasms in the retromaxillary region.

In the investigation of neoplasms we must first of all try to find out the type, their extent and if possible their origin. Of the benign tumours, osteomas are the commonest. Strangely enough, reports of surgical removal of such tumours are still being published. From a differential diagnostic point of view, fibro-osteomas are much more important. In these, pressure atrophy may be so severe that the radiologic picture can give the impression of a malignant neoplasm accompanied by destruction. Certainty can only be secured in such cases by biopsy. The knowledge of these conditions is of great importance from the differential diagnostic view-point since it is not possible to determine the nature of the process simply on the basis of clinical symptoms.

In malignant tumours, there is usually a complete opacification of the affected sinus by the time the patient comes to roentgen examination and there is nothing to distinguish it from opacification produced by fluid or thickened mucosa. One must therefore carefully examine the sinus walls for evidence of decalcification and destruction. The malignant tumours usually originate in the maxillary-ethmoidal angle and grow out towards the nasal sinus, the frontal sinus and orbits, or posteriorly towards the sphenoidal bone or through the posterior wall of the maxillary sinus out into the fossa pterygo-palatina.

Treatment of the tumour depends on how widespread it is. If the tumour is small and well defined, according to our experience the best results are obtained by combined radiotherapy and surgical therapy; only radiotherapy can be offered in a case with a widespread tumour. Pathologic bone changes of the great wing of the sphenoid and of processus pterygoideus imply that the tumour is too wide-spread to be extirpated from healthy tissue.

I have now set forth in brief our experience in Malmö. My views are of course coloured by my personal experience. It is obvious that these problems can be considered from various points of view, and what I have said is by no means exhaustive but should rather be regarded as a few points which I thought might be of current interest.

Advances in the Science of Communications as It Relates to Medical Writing

THOMAS S. WAINWRIGHT
New York, New York

Altered from a presentation at the American Medical Writers' Association Conference, Chase Hotel, St. Louis, Mo., Saturday, October 3, 1959 and published in part in Mississippi Valley Medical Journal, January, 1960.
Mr. Wainwright is Vice President of Kastor Hilton Chesley Clifford & Atherton, Inc., New York, New York.

I HAVE MADE a systematic run-down of all the major communications sciences. I talked to a lot of people in New York and elsewhere, always looking for the new. Communications sciences fall into the broad categories of the physical and the psychological. I wish to stress what is new physically, and what fits the service of medicine in the three prime areas of (1) Medical Teaching, (2) Public Health Education and (3) Medical Public Relations.

Closed Circuit Television

Specifically, you will have to fit each topic into its useful niche. Closed circuit television, for example, is expensive, but it is amazing. A five-year-old science, it is burgeoning in use in commerce and industry. In fact, for the first time next week, the Army Quartermaster Corps will use it for auctioning off of surplus government equipment.

Originating from three locations, the Army Engineer Depot at Granite City, Illinois; the Air Force Depot at Shelby, Ohio, and the Philadelphia Naval Ship Yard, the eight-hour-long sale will be wired into auditoriums in New York, Philadelphia, Chicago, St. Louis, Columbus, Ohio; and Boston. A two-way audio circuit will permit the bidders at the six viewing locations to speak up.

You know how closed circuit television works. Via telephone lines, the audiovisual signals are sent from the transmission point or points to selected locations, usually theatres, auditoriums or hotel meeting rooms. Screens can vary from monitors, similar to your home TV receivers, accommodating an audience of ten to twenty persons, to a four-sided giant screen, each side measuring 50 by 65 feet such as has been used at Madison Square Garden in New York to reach thousands of people under one roof.

Closed circuit television is not a communications technique new to the medical profession. In 1955 Smith-Kline & French introduced their "Videclinic" to 20,000 heart specialists in thirty-five cities. Since then, there have been eighteen or twenty others sponsored by pharmaceutical manufacturers, the most extensive being that of Upjohn's "Grand Rounds," a telecast to 35,000 doctors in fifty-three cities; and with 200 kinescopes subsequently shown at local medical meetings, reaching an ultimate audience of 100,000 physicians, or about one-third of the U. S. total. A kinescope, as you know, is a motion picture copy of a telecast, suitable for 16-mm. projection.

A single maximum hook-up of closed circuit television could simultaneously reach three-quarters of the 226,000 M.D.'s in the United States. But who would pay for it? I am sorry I cannot furnish information on that too. But the president of SUNOCO, the Sun Oil Company, estimated that a $500,000 convention could be held via closed circuit television for $200,000.

An editorial in the *A.M.A. Journal* of January 1, 1955, said: "The increasing demand for refresher and other special short courses reflects a desire on the part of practicing physicians to receive well-organized, systematic presentations of new medical knowledge. However, physicians in both urban and rural areas find it difficult to absent themselves from their practices to attend

post-graduate courses without curtailing the effective medical care they render to their communities, to say nothing of the economic losses they may incur through the loss of practice and the expense of travel and maintenance while away." The editorial continues to say that television may "provide a solution to this problem as a medium through which medical centers can extend the walls of their laboratories, lecture halls, hospital wards, and clinics to encompass virtually all the physicians in the country."

It hasn't happened yet, but I am sure the ingenuity of the medical profession can find a way. And the advance of the science itself is making the finding easier.

If you want more detailed information on conventional closed TV you can communicate with Mr. Nathan L. Halpern, President of Theatre Network Television, Inc., 575 Madison Avenue, New York City. I mention this organization because they handle about 85 per cent of all closed circuit television in the United States.

Two-Way Telephone Circuits

Now here is a less costly way to accomplish something akin to closed TV, but at about one-fifth of the cost. A demonstration or illustrated lecture can be presented, and questions asked and answered with as many far-flung cities hooked up as you might want. This is executed with two-way telephone circuits, and a co-ordinated use of 35-mm. film strips, projected with ordinary equipment.

In each of the audience cities, a projectionist operates the projector, changing the frames at word cue or at an ultrasonic signal. Mikes and speakers are at all audience locations, so questions can be asked from any audience group, and answered from the demonstration city, or vice versa.

Such telephone hook-ups are arranged through the "long lines" department of the telephone company, but if you want further data I suggest you communicate with Mr. Robert E. Taylor, President of Research and Training Corporation, 331 Madison Avenue, New York City. They pioneered this system.

Pay Television

I'd like to make an interpolation at this point. My opening references to closed circuit television are related to what I wish to call to your attention now with reference to Videotape and pay television. Medical communications have two basic audiences. One is the profession itself; the other is the public.

In the first case, it is obvious that TV is an ideal medium for teaching because it can demonstrate simultaneously to masses of physicians. In the second case, the visual impact and popularity of TV are important, but more important, is the simple fact that more and more free television "time" is going to become available to the medical profession—for the purpose of promoting public health, and the important position of the physician in the community.

I shall talk about pay television first, and then about the electronic camera and Videotape. By way of preface, you know that Commercial Television is controlled by the Federal Communications Commission, and is required to devote a certain amount of its broadcasting time, gratis, to "public service" programming. Much of this time could be used to promote public health and the role of the physician in this vital area of national welfare; but to my knowledge at least, it hasn't been.

Now, pay television is coming fast, and while not subject to FCC regulations when direct-wired, it plans to devote one-third of its facilities to "public service" programming. Telemeter, Inc., a subsidiary of Paramount Pictures, has announced operation in five cities this autumn with a minimum of 5,000 wired homes in each city. There are other pay TV organizations like Skiatron and Zenith, and they appear to be moving too.

Pay TV, as you know, may be wired into the home, or broadcast. If broadcast, it is "scrambled" in transmission, and "unscrambled" at the receiver. Both wired and broadcast varieties are coin-machine controlled, so the viewer pays for what he wants to look at, and there are no "commercials." Because the broadcast variety will fall under FCC regulation, no doubt it will be required to give a certain amount of free time to public service programming, opening up more such time, in addition to what is available now from commercial television stations.

Telemeter

Telemeter, which will be wired directly into the home, and will therefore not be under FCC

control, will nonetheless devote one-third of its time to public service programming. Here is the way it will work:

Each home will be wired with three channels, as follows: (1) movies, (2) current events and (3) public or community service programs. The Telemeter subscriber will have to pay to see a movie, or a wrestling match, or what ever is offered on Channels 1 and 2, but Channel 3 will operate "free." Channel 3 will have a continuous showing of public service material, and will be used to announce periodically the coming "pay attractions" and the prices. This Channel 3 will be the one open to you, and it will require hours and hours of material.

Videotape

All this ties in with Videotape. You know how it works. Both picture and sound are recorded in magnetic impulses on acetate tape. Picture can be in black-and-white or color. Videotape made it possible in America to show hours later on television the historic exchange between Khrushchev and Nixon at the Moscow Fair. Videotape, unlike optical motion picture film, requires no developing. You can project the pictures immediately after recording.

A Videotape camera costs only about $1,000. The costly element is the recorder, the machine to which the camera is connected, which records the pictures and sound on the tape. A recorder costs about $65,000.

However, by means of telephone lines, a Videotape camera anywhere can be hooked up to a recorder anywhere; and very soon almost all TV stations will have Videotape equipment. A recent release reported that forty-three educational television stations have been equipped with Videotape recorders through a Ford Foundation grant. In addition to studio-located recorders, there are mobile units with recorders mounted on trucks.

Once a Videotape has been made, it can be shown on any TV circuit—commercial, educational, pay, closed or broadcast. Further, it can be converted into a kinescope, or kine, which can be shown with any standard motion picture projector.

I will have to leave up to your ingenuity and your resolution the application of the information I have passed on to you. But it seems to me that certainly a state medical association could afford to invest $1,000 in a Videotape camera. Possibly even a county chapter could.

I know many physicians who are handy with a home movie outfit. A Videotape camera is not radically different, cinematographically speaking. Certainly, co-operation can be sought from TV stations for recording arrangements. Any additional information you may want on Videotape equipment may be had from Ampex Corporation, 934 Charter Street, Redwood City, California.

The point is that every medical group in the country can gear up to build a library of Videotape recorded material that can be used in two directions: (1) to the public on public service TV time; and (2) to the profession itself through closed circuits and/or kinescopes. If, as and when the Pay TV circuits are working, it is possible that "selective use" of the medium could be worked out, so that on special occasions, professional demonstrations could be piped directly and privately into the homes of physicians only at an appointed hour. If you want to know more about Pay TV, you can write International Telemeter Corporation, 2000 Stoner Avenue, Los Angeles, California.

Organization and Economics

At this juncture, I should like to express several points of confusion, if not of amazement. I have tried to report to you new communications techniques, and do it in such a way as to indicate free, or at least relatively economical, means open, or opening up to you.

I have even asked: "Who would pay for it?" I have said many M.D.'s are pretty good amateur photographers, so maybe they could operate Videotape cameras. I have talked to you as if I were addressing a group of noble indigents like the Franciscan Friars; men with a good cause but no means.

Now, I ask myself. "Why?"

Let's take a long and honest look at medical communications, and what purpose they should serve, and who is really responsible for effecting them.

It appears to me that the medical profession itself, perhaps through the AMA, could effect a corporate attitude, holding that medicine, like a business corporation, has the responsibility for keeping up with technical advancements, and has a stake in its "market"—public health.

The question has been asked, "but who pays for it?" Pharmaceutical companies have done yeoman duty with closed circuit TV, but it must be admitted that what they have done has been slanted with self-interest.

If the medical profession could acquire the viewpoints of a service corporation, it could and would attack and solve the problems I have mentioned. If the real issues in medicine are such considerations as socialized medicine (and how to avoid it) and professional integrity (and how really to achieve it), then it behooves the medical profession itself to find ways and means to use new and appropriate communications techniques to cut through the competitive din of frequently contrived information often biased by self-interest, both in the area of postgraduate training, and of public health education.

Consider the corporate operation. Income is ploughed back into research, new product development, plant expansion, promotion — many various types of investments which insure the kind of public satisfaction which in a competitive society, and which philosophically, in fact, is the basis of existence for us all, and which is tantamount to serving at all.

As an example, consider the Columbia Broadcasting Company. This is a service corporation; it has no products, its function is vitally concerned with the public interest because it deals with the public mind. But it is controlled by the government, and criticized by all kinds of pressure groups and crackpots. Yet, CBS does not hope for solutions to its problems. It promotes itself, improves itself, makes sure that its corporate P&L statement is sound, and thinks constantly of the service it is rendering to the public in competition with NBC, ABC and other TV facilities because if it really fails to serve, annihilation is its destiny.

Is the medical profession actually in any different position? You can say, "Well, information, and certainly entertainment, which is a large part of TV, is not really essential."

So let us take transportation, as another example. Transportation is incontrovertably essential. You are all familiar with the vast sums spent by the automobile industry for research, development and promotion. For what reason? To make a profit? Of course. But in the process, to serve the needs of people who must have transportation to live, work, maintain the economy and enjoy themselves. Are the aims of the medical profession different?

I am not clear about the distinction between the so-called "professional" and the so-called "commercial" endeavors. Certainly, the physician may not take liberties with the life and limb of his patients without violating his code of ethics; but neither may a motor car maker manufacture an automobile with square wheels without violating his code of ethics, as well as everybody's common sense.

Speaking of money, there are 226,000 physicians in the United States. I have not taken the time to ascertain the average income of doctors, but guessing, if it is $20,000 a year, then aggregate income totals $4,520,000,000; if $10,000 then $2,260,000,000. Few corporations spend less than 1 per cent of gross income for advertising and promotion (not including research and development), many spend as much as 20 per cent. One per cent of $4,520,000,000 is $45,000,000; of $2,260,000,000 it is $22,000,000.

Can you say, "Physicians, collectively, are not a corporation"? If so, then am I to conclude that because there are 226,000 physicians there are 226,000 medical corporations?

In the world of commerce, there is an answer to this too. There are associations in business—I'll cite the California Fruit Growers Association, just to name one—that do function like corporations, as cohesively, as intelligently, as efficiently, as profitably. If they didn't, their members, as individuals, would be stunted, if not annihilated.

I was going into other frontiers of "new advances" in the science of communications. I am especially interested in the psychological sciences such as ESP, subliminal communication, adult motivation through children, Freudian manipulation, symbolism and other techniques, some somewhat proved and some totally unproved. We use them with varying degrees of success in advertising, and I believe you should take a second look at all of them, for certainly "selling" medical care and family health are just as important to the nation as selling corn flakes, soap or filter cigarettes. But whatever the product, the "sell" must be strong and clear and "motivating."

If you think what I have talked about (even without getting into weird psychology) is *avant garde* akin to Jules Verne, or Buck Rogers, just bear this in mind. Unless they lied, or we can contradict them, there's a Russian hammer-and-sickle insignia on the moon right now. Who says I'm ahead of my times?

Preventive Psychiatry—Present Status and Future

CARL P. MALMQUIST, M.D.
Minneapolis, Minnesota

III

This section will discuss and evaluate the techniques used in the application of mental health principles to the detection and prevention of mental illness, followed by a discussion of the application of these techniques to the various key groups in our society in which any preventive program must be applied. The need for a corrective emotional experience besides a logical and didactic explanation has been mentioned as necessary for any successful program of mental hygiene. The basic objective of such programs is to modify attitudes and unhealthy behavior secondary to unhealthy attitudes, and this is essentially an educational process where one person feels or recognizes a need, and another has a special training or background which can help fill the need. It is thus seen that the main instruments used in mental hygiene programs are not specialized laboratory equipment but specialized personnel. Some of the strengths and weaknesses in the personnel used are pointed out:

1. The psychiatrist, being a doctor of medicine initially, has normally taken at least three years of specialty work. Until recently, all this time could be spent in a mental hospital with the American Board of Psychiatry and Neurology only requiring six months' work in an out-patient setting.[31] Psychiatric training in itself does not necessarily mean the individual qualifies as someone effective in the role of a preventive mental hygienist. Depending on the place of training, there might be little instruction in psychology, anthropology, and related social sciences, and none on the growth and development on the normal personality. Until a short time ago there was little opportunity for the psychiatrist to take an active communal role since most mental hospitals were put in rural areas and "isolated" as much as possible, and the remainder of the medical profession did not seem ready to admit this specialty into the role of guiding and setting up principles of desirable behavior, let alone the general public. Most psychiatrists have thus had little public health training or experience, and they are not all equipped to understand the epidemiological and statistical methods a mental health program needs. There is also such a thing as an "epidemiologic temperament" in which one must be as objective as possible relying on one's reason for progress, while a "psychiatric temperament" must have more dependence on intuition; the latter predisposition with psychiatric training can produce difficulties when psychiatrists practice in the public health field.

At the present time, much preventive psychiatry is being done by people not specifically trained in this area. Well-trained psychiatrists and psychoanalysts speak on mental hygiene without any knowledge of education or the techniques of mass communication. Conversely, other people working in this area often use psychiatric and psychoanalytic theory without being aware of their meanings and implications.[32] Despite these limitations, the psychiatrist is usually the person expected to assume the leadership role in mental health programs, probably because his medical status gets more response from the medical profession and more acceptance from the general public. It must also be remembered that the role of the psychiatrist has changed immensely in the past forty years due to several factors such as two world wars and the Korean conflict that brought out the great amount of disability due to emotional problems. The contributions of psychoanalysis not only as a method for the study and treatment of personality disturbances but as a means of research into the nature of behavior as such, the increased awareness of the public towards emotional disorders and the contributions of psychiatry, the development of psychosomatic concepts of physical illness that have brought all the traditional concepts under review from a new orientation, and the success of public health measures in the control of infectious diseases has pointed out the need for progress in the field of mental illness to the involved professions and the public at large. At the

Parts I and II appeared in the April issue of MINNESOTA MEDICINE.

present time, the problem is one of getting enough qualified psychiatrists to meet the ever-growing demand for psychiatric services, not only with hospitalized and non-hospitalized patients, but as administrators, superintendents and in subspecialties such as industrial and forensic psychiatry, as well as in child psychiatry where forty new men are trained each year at a rate that would take fifteen years to staff the 600 clinics thought needed even excluding the residential treatment units.[33] The 1958 *American Medical Directory* lists 6,249 psychiatrists in full or part-time specialty, and estimates put the deficit at 50 to 100 per cent; about 550 new psychiatrists enter the field each year which would take twenty years to double the present number ignoring increased demand from population growth alone. From this picture, some have advocated decreasing the demand by encouraging people not to seek professional help for the minor discomforts of life like headaches, insomnia, irritability, nail biting, social drinking, et cetera.[34] It is from these facts that much responsibility for preventive mental health must be shared and shifted to other professional personnel.

2. Psychologists have a useful role in any mental health program, but here the wide variation in training is again prominent. There is variation present from the different academic settings where training takes place, and also by the degrees from the Ph.D. in clinical psychology to those with little clinical or outpatient experience. Clinical psychologists have a good background in research methods and design, and with greater emphasis on having all its members holding a Ph.D. degree with at least a year of clinical training, they have much to contribute. He is often well-trained in evaluating and meeting community needs from his role as psychological consultant, psychotherapist, and his research in various aspects of personality functioning in health and disease.

3. The psychiatric social worker has had two years of specialized training for a master's degree, and has had much emphasis on the intricacies of interpersonal relations with families and in other group settings. Through her interviews with families, it was found she could change their attitudes so they could better assist in the therapy of a patient, and plan for the return home of a hospitalized patient. In dealing with children, it has been the customary function of the social worker to treat the parents while the psychiatrist handled the child, thus giving him or her a unique opportunity to see family organization or disorganization, and how pathology in a parent laid the groundwork for mental illness in a child and how such behavior could best be modified. The expanding position of the psychiatric social worker is allowing an increased opportunity for them to take a more active part in mental health activities by participating in the educational and training programs for other professional personnel, such as medical students, medical and psychiatric residents and nurses. They can contribute the effects of social and economic stresses on patients and their families, and what is or should be available, the nature of social, health, employment, recreational, educational, vocational, legal and other resources in the community. Again, the capabilities of the individual social worker will largely govern her contributions.

4. Public health nurses working in the mental health field have been in existence only since 1948.[35] They have at least one year of special training beyond their R.N. and baccalaureate degree, and the nature of the training varies depending on where it is taken as some schools have different programs, some emphasizing public health sciences, others nursing supervision, or social work; all of them do tend to stress growth and development, and community facilities for dealing with mental health programs. From the short time these specialists have been in operation, the exact roles and accomplishments are not yet determined. It appears that they act as consultants to staff members on problem cases, decide if special referral to psychiatric or social clinics is needed, orient new nurses toward the mental hygiene objectives of her department, teach in local health departments about psychiatric clinical services available, and prepare nurses to teach the community how to use its psychiatric resources more effectively.[36]

5. Public health officers are usually physicians trained to deal with disease and promote health on a community level. They have had much training and experience in putting health programs into action. Inasmuch as their responsibility is for public health, they have a logical and contributory role to play, although some psychiatrists seem to feel that mental health is a separate area from public health responsibility.[37] Some even believe that the state psychiatric hospitals

with a pool of psychiatrists should be responsible for state mental health programs. However, the need for public health people is apparent when the differences between pyschiatric treatments and mental hygiene are noted, as well as the different job of administrator and public education. As mentioned above, in many communities the psychiatric hospital is isolated from the community, as was the psychiatrist from the medical community until recently, and thus the public health departments have a vital contribution to make.

6. Psychiatric nurses usually function in a hospital setting, but their influence on mental health may be important not only there, but in their other duties such as administrators, educators of nursing students, and coordinators of occupational and recreational activities. Although most nursing schools now include some work in psychiatry in their training programs, there has not been any decrease in the pathetic shortage of nurses in mental hospitals, and the need for graduate training in this field and something to take the place of the now deserted state hospitals system of producing psychiatric nurses is needed. Occupational and physical therapists also have roles in mental health similar to the psychiatric nurse.

It is seen that the use of different types of personnel, each specialized, is utilized for putting ideas into effect with populations. Meeting the public at the local level is the crux of their job in preventing mental illness, and this is done in cooperation with various health department personnel, the functional arrangements of which will not be discussed. In many fields of public health, the police power may be used to secure ends, such as in environmental sanitation and immunizations, but preventive psychiatric programs have many more similarities with programs for the early detection and prevention of cancer, that is, they must be based on teaching and persuasion, inducing a state of mind in the public that makes it want to carry out scientifically demonstrated and recommended practices, and this involves altering attitudes. Although the administrative details of organizing a community for a mental health program will not be covered here, it must be said that "the essence of public health at all levels is the building of an understanding of influential persons as to what it is about and why."[38] One of the most important influential persons to have in any program is the general physician whose support or rejection can make or break any program as his enthusiasm carries the mental health principles into his practice and influences his patients and their families, and in turn their children, relatives and friends. This is of added significance when it is realized that the vast majority of people whose health care requires some psychiatric understanding will never see a psychiatrist, but will see a general physician and receive whatever psychiatric help he can give them or get them.[39]

Before the techniques used in mental hygiene are discussed, a few fundamental principles should be stated. It must not be thought that all the various approaches used are ends in themselves as their effectiveness is only to be judged by the success they have in altering basic attitudes inimical to mental health. As Zilboorg has stated, "We commit a serious methodological mistake when we assume that ideas as such may serve as promoters of mental health. Even ideas about mental health cannot do much because ideas are not movers of instinctual forces but rather their representatives. . . . Man's overestimation of his own intellect has become combined with our recent overestimation of psychiatry and thus led us into a methodological path which is extremely popular and just as extremely devoid of scientific validity or practical potentialities."[40] Thus, it cannot be assumed that discussion groups and just talking about behavior problems and mental health have ever accomplished anything; it depends on the content of the discussions, and more important, with what intensity of feeling and sense of identification the discussion goes forward. This implies that the goals of mental health programs must be clear because the techniques are always subservient to this end. Leadership for the various programs will have to come from the specialized personnel mentioned previously, along with key community figures. Some of these people will be more effective than others in achieving their goals, and for some, certain approaches are more effective, such as working in small groups rather than with a large audience. It is well known that in any general educational process the more emotional the involvement that can be aroused, the more intellectual curiosity will be stimulated. In mental hygiene work, the effect on attitude is not just an aid to learning information, but one of the ends of the process. Thus, it is not the objective for parents to find out that their children will go through a period of negativism and stop there, but they should "attitudinally" accept this as a step toward

adulthood and individuality and appreciate that their child has a developing personality for which they have a responsibility.

Some of the accomplishments and shortcomings of the different techniques used should be mentioned.

1. Pamphlets are a well-established method attempting to influence the public. In regard to the success of getting people to read these pamphlets, it may be countered that no one has proved how effective this is despite the factual evidence of large numbers of pamphlets being read. This technique appears to have most of its effectiveness when the publications are directed specifically at a particular audience whose needs are known, such as the attitudes of pregnant women about their pregnancy and future child and publications for parents on the behavior and needs of children at different age levels. However, for people with behavior problems reading a pamphlet may not be enough to get them to recognize their pathology, or seek help if they do.

2. Posters can be mentioned as a form of modified and abbreviated pamphlets. All the criticisms directed at pamphlets apply here and more so. It appears that their main effectiveness is in raising money, but they may on occasion be a stimulus for taking some action.

3. Books are similar to pamphlets, but the wide variety available make them more adaptable to specific groups and thus more effective. Guide books on child care and behavior are usually effective in a mental health role in that they eliminate baseless anxiety and thus a stress upon the parents that could contribute to mental illness at some time. The effectiveness of books that attempt to explain behavior by a theoretical psychological theory is questionable and those that use psychiatric terms, such as the defense mechanisms, may merely increase the facility the reader has in using catchy terms without recognizing the unhealthy use being made of such mechanisms or how to control them. The probable worthlessness, despite their great popularity, as evidenced by best-seller lists, of books that advocate some psychological hobby or mechanism to relieve tension and increase happiness is disturbing. Just confining ourselves to those written by seemingly sincere people, they are based on the conclusion that techniques that give the writer comfort must help everyone in the same way. More damning is the way these uncritical ideas are exploded on the public by high-pressure advertising and sales promotion; if only a part of the money used to promote the sales of these books and the money spent on purchasing them could be diverted to mental health research, progress would be in order. The damage they do on an individual basis is also important as for the person whose whole effort and persistence are devoted to keeping a precarious, borderline adjustment, reasonably satisfying to himself, the "rah-rah" attitude of such books may be disquieting and contribute to "negative thinking."

4. Newspapers and magazine articles vary from worthwhile to the sensationalism that equates psychology and psychiatry with sex. The articles are effective so far as they alter harmful attitudes or stimulate the need to alter them; they may also have a role in undertaking reforms when needed, if this can be done without undermining the morale of the involved agencies.

5. Radio and television are communication media par excellence for reaching the public and involving them emotionally during the learning process. It is not the emotional involvement for its own sake that is the objective as all good and many poor films and plays do this, but it is hoped to get the audience identifying with one or another of the characters so that each member lives through an experience as if it were his own. The more this identification can be promoted, the more effective the program is in terms of altering attitudes and behavior. Television has the advantage over radio in this regard in that it shows the actor or speaker and makes identification and consequent emotional involvement more complete while the whole range of gesture and expression may also be used. Speeches and lectures are the least effective method of presenting content and molding attitudes, while a play performed by skilled actors with a strong illusion of reality is the most effective; these may often be reinforced by having a nationally known figure comment on the play at the end, pointing out its lesson and the need for its being taught, or simply lending prestige to the presentation. Documentary presentations with a mental hygiene theme usually get large listening audiences, but aside from this, their effectiveness needs more evaluation. A recent study evaluated the reactions of approximately 15 per cent of the population of the United Kingdom to a television series dealing with mental illness; the positive results obtained

were the spread of knowledge on the treatment of mental illness with an increase in the confidence that doctors could cure mental illness, and also an increase in the willingness to associate with the ex-patient.[41] There is evidence that communications to the general public are least effective when they raise a high amount of anxiety in the listeners, and solutions to the problems raised are not suggested. High anxiety messages *per se* tend to depress public interest.[42] Spot announcements are probably better adapted to getting contributions than to teaching. Discussions following performances of plays are often very useful in that members of the audience can identify first with one character and then another, and from the fact that they are not really the characters, a level of objectivity may prevail that usually leads in the end to a rational yet "feeling" solution of problems presented.

6. Motion pictures are very similar to television and range from maternal neglect of the newborn to the feelings of rejection of the retired, skilled workman. When used for evocative purposes, it was found that discussions were needed as the audience often left tense and guilt-laden. Discussion allowed observers to recognize that others have feelings like themselves and feel anxious because they could not achieve the satisfactory attitudes usually portrayed at the end of the films. A good discussion leader is essential to focus attention on certain aspects of the film, and recognize the personal emotional involvement in the various discussants and bring out how others have similar feelings. At times, the leader must curb a situation that is becoming too intense emotionally or that is becoming embarrassing or is overexposing the personality needs of someone, and similarities to group psychotherapy are then obvious. The effects of films are difficult to evaluate because it is easy to detect if the audience enjoyed the film and discussion, and if they were emotionally involved; but if a significant change in their future behavior has occurred is debatable, although most authorities seem to agree that a lasting effect has been created in a good proportion of the audience.

7. Lectures allow very little audience participation, yet they can be effective in allowing a large audience to see and hear a popular figure support some theory or popularize an idea. This is an excellent medium for the rational, unemotional presentation that has a place in mental health education although it must be supplemented by the techniques discussed above. Once again, objective evaluation of the effectiveness of this technique is badly needed.

8. Discussions have been mentioned along with motion pictures, and they may also be used with a parent-teacher group, churches, women's clubs, et cetera. These can range from the non-directive type with the group formulating its own ends as it moves along to a more structured discussion with various topics to be covered and summaries of progress. Crucial to the success of discussions are highly skilled leadership, and although it is often said that failure of the discussion or dropping out of members is due to sensitivities of group members, poor leadership is probably just as important. It is believed that small groups, meeting at regular intervals are the most efficient technique for learning the insights into behavior and attaining attitudes needed for satisfactory living. These various means of changing attitudes to promote mental health all involve the effect on the individual listener or participant, and it must also be mentioned that other personality molding forces are present in our cultural, sociologic, economic and political areas that affect people directly or indirectly through their parents, and changing these forces via the techniques mentioned here is not envisaged. For the people with deep emotional conflicts, the importance of general physicians cannot be underestimated as it is through them that such people can be directed to psychiatrists or agencies and an attempt made to stop the passing on from generation to generation, both longitudinally and horizontally, the behavior problems that plague them.

IV

In this section, a brief consideration will be given to the various key ages, groups, and institutions in our society where the prevention of mental illness must be effective if any program is to be successful. In the pre-natal period, the prevention of mental illness should be approached on both an organic and functional basis. For the former, public health measures are of prime importance and should have as their aim the prevention of maternal nutritional deficiencies, prevention and proper treatment of toxemias and medical conditions in the mother, avoidance of contact with rubella patients or use of gamma-globulin when exposed. It is also believed that some cases of behavior problems may result from

brain injury due to complications of pregnancy and childbirth, such as eclampsia, neonatal asphyxia and birth trauma. A recent study from Baltimore compared the birth histories of 1,151 behavior problems with 902 matched classmates from public schools and found significant abnormalities of the prenatal and paranatal periods in the former which they hypothesized as due to minimal brain damage.[43] The emotional attitude of the parents is also important during a pregnancy, particularly in regards to the effect they may have on the future life of the child and in respect to the current and future relationship of the parents toward each other. This is a fruitful area for educational efforts since the emotional relationship is clearly present and often recognized in respect to fears the mother has about her capacity for being a mother, sexual and other relations with her husband during pregnancy, and caring for the newborn.[44] Pre-natal clinics are a suitable and logical place for such discussions to take place, and these usually include the question of sex education for older children in the family and the almost inevitable sibling rivalry.

Well-baby clinics have a role in mental health promotion up to the time when the child enters school. The physiologic and emotional changes going on in this period are monumental as in this period the child changes from the dependent, incoordinated, helpless infant to a relatively independent person who should be capable of spending some time out of the home, and who can act and plan in a purposeful manner. All the requirements needed for healthy growth and development will not be mentioned except to say that the well-baby clinics are a place where a great deal may be done to promote this. Most pediatricians and psychiatrists now seem to feel that "rooming-in" procedures lessen maternal anxiety about infants and gives the infant more attendance to its needs than when it is put in a nursery. It is also believed that this promotes ambulation earlier by the mother and has an effect of decreasing the incidence of post-partum depression. The needless anxiety and feelings of failure produced in mothers who were unable, or did not desire, to breast feed due to the recent crest of popularity, now seems to be happily waning. Although there is not definitive proof that a mothering figure is needed for healthy emotional development, the evidence is in its favor and no one has suggested the absence of such a figure as a model for raising children. There is also much to suggest impaired parent-child relations contribute to mental illness, but it is not believed to be the role of a non-specialist to pry deeply into the unconscious factors at work, but rather to refer to child guidance clinics or private psychiatrists if this is indicated. A physician can offer parents a reassuring relationship regarding their adequacy as many parental reactions are the result of excessive anxiety, and he can also offer children a relationship with a non-relative who has prestige and who recognizes their existence independent of their parents.[45] Many varieties of childhood schizophrenia are now being recognized with the most common clinical picture showing maturational lags, autism, pan-neuroses and paranoid psychopathic behavior.[46] The problem of differential diagnosis in such cases between congenital defects, brain injury or emotional disturbances may be very difficult. Bender points out that it was the hope of workers in child guidance clinics to reduce delinquency and disturbed behavior in youth, and mental illness later, by preventive work in these clinics, but there is no statistical evidence that this has been accomplished. She believes the clinics have served a useful role as a place for parents, teachers and child workers to go for discussion and guidance with their problems, and as a diagnostic center that may offer special clinical facilities for epileptics, reading disorders, cerebral spastics, retarded children, and short term treatment of acute childhood problems.

Increasing knowledge of personality development has tended to stress the general family atmosphere more now than the specific behavior of parents, and the extent to which educational programs can modify the family atmosphere is a matter of controversy. No study has yet shown a reduction in the incidence of any personality disorder following educational programs for parents.[47] It would be possible to experimentally detect if differences in parental attitudes and behavior with respect to children really modify the incidence of neuroses and psychoses by evaluating different culture groups that have varying parent-child relationships. This would demand three formidable technical advances: (1) There must be studies of actual child-rearing practices unaffected by assumptions drawn from the nature of adult personalities but based on direct observations. (2) A distinction must be made between mental illness and the assessment of mental illness by different cultural groups. (3) There must be an adequate

technique for determining who is ill in different cultures.

The mental health of the school child is a subject that has been written on voluminously although often with a superficialty and too much controversy. It is estimated that 1 per cent of all school children need psychiatric treatment of severe symptoms, and 10 to 20 per cent need careful diagnostic work of lesser symptoms at some time in their school career.[48] Allowance must always be made for the child who does not fit within the range of standard deviations for "normal," particularly in regards to speech and reading disorders and those slightly below average mentally so that conduct disorders and frustrating failures may be avoided before they occur. Most educators would undoubtedly agree that the aim of education should be to make experiences and knowledge lead to a strong personality structure besides the factual knowledge gained. The best way of doing this is believed to be by selecting teachers whose good mental health will serve as an example for the children to identify with, and training teachers to have an understanding of emotional growth and development. It is apparent that these criteria are not often achieved especially in a period of teacher shortage and population growth. Various techniques have been advocated for promoting mental health in schools, such as student counselling, visiting teacher systems that get social workers into the field, and human relations courses that discuss emotionally charged situations. It has been recognized that young children operate more on the basis of affect than intellect and certain factors in classrooms help to avert emotional conflicts such as keeping the room pleasant materially, having friendly teachers who encourage friendliness among the children, helping the child to feel personally significant, and having a teacher sensitive to children's feelings. There should also be opportunity for children to express their emotions via writing, art and music, dramatics, physical play, reading and discussions. Some also advocate instruction in principles of human relations and behavior at a level appropriate for the age group.[49]

More controversial is the matter of incorporating sex education in classrooms as this is an area where most teachers and many parents are unaccustomed to face issues directly and are consequently unprepared to face them with children. It is apparent that methods of teaching mental health education are not standardized, and there is a need for much effective research. A study involving 350 school systems across the nation revealed 80 per cent had no classroom discussion of mental health, 85 per cent of the schools where it was discussed had no staff personnel trained in mental hygiene, and in 17 per cent of the schools there were no mental hygiene services of any kind.[50] Until such knowledge is available, a compromise must be adopted with the responsibility on the teacher for pushing some children as needed, pulling others and referring those that need it.

With such crucial responsibility, it is apparent how a teacher can easily foist many of her own emotional problems on to her children and every way possible for ferreting out such teachers must be pursued. In view of the teacher shortage, it may be better to have larger classrooms temporarily than allow children to be reinforced in their emotional handicaps. It is not enough to say that the per cent of emotionally disturbed teachers is less than their percentage of the population as their influence is exerted on millions of children in their classrooms. Using the most conservative figures available from studies in this area it was determined that 9 per cent of teachers were in need of psychiatric care,[51] and 25 per cent unhappy enough so they would not go into teaching again.[52] From these figures, approximately three million children are exposed each day to teachers distinguished sufficiently so they should not be around children. Experimental work has shown that mental health workshops for parents and teachers under the direction of a psychiatrist or a dynamically oriented psychologist are effective in changing attitudes and achieving rewarding results on psychologic tests, and such studies are an example of how scientific methods can be applied in evaluating mental health techniques.[53] Dr. Stevenson points out that although health has been at the top of all lists of educational objectives for the past forty years, it has not yet received the attention it merits, and mental health suffers more than any other part of school health work. In summary, efforts should be made to promote mental health in schools for all children by remedying unhygienic attitudes of some staff members, undemocratic procedures in the administration of schools, exposure of children to too much or too little stimulation, and prejudicial community attitudes that infiltrate the school. The mental health of college students has also been an area receiving increasing attention although the need for such special selection

from others in their age has not been adequately demonstrated.

Almost everyone is aware of the great increase of people in the seventh, eighth and ninth decades so the numerous statistical studies will not be cited. It is also being realized that longevity for its own sake is hardly a worthwhile goal. The mental health of the aged is a voluminous subject and only a few factors relevant to the prevention of mental illness will be mentioned. It is often a subtle problem in differentiating mental abberations from eccentricities and having to decide if impaired memory, labile emotions or disorientation need care in a mental hospital or can be managed in a rest home.[54] Many of the psychoses of youth and middle age reappear in later life, and thus an awareness of past mental conditions can often alert the physician to mental illness. Many psychologic abnormalities are produced by the increased susceptibility of the old patient to drugs and nutritional deficiencies which can be prevented. The emotional needs of older people do not differ greatly from others although their distorted perceptions, goals and activities make it difficult for others to see what they want or are trying to get, producing an indifference or hostility of family, community and physicians stemming from the anxiety and resentment aroused by the helplessness and apparent lack of resources of the elderly.[55] There is much room for improvement in constructive mental health programs for old people, and there are many ways these people can be helped to lead a satisfactory life with prevention of mental breakdowns to the benefit of themselves, their relatives and the tax-payers, but prevention must start years before as it had been shown statistically that poor, foreign-born, uneducated, unmarried, non-white urban dwellers are more likely to be hospitalized in later years.[56] The mental health problems arising from old age itself are only part of the problem as those problems due to dependency and the present make-up of society also contribute.[57] The value of pre-retirement counselling has not been appreciated along with the need for developing new interests, activities and participating in community life at recreation centers, Golden Age Clubs and church activities, but without a foundation being laid for such activities much earlier than old age their effectiveness must be questioned.

With all the recent talk about industrial hygiene, it is interesting to see how little mental hygiene has actually been incorporated in such programs. This may stem from the goals for which such plans as do exist are devised, for they seem to be primarily interested in obtaining increased production from workers by various means such as improving worker and management motivation, building morale, and decreasing labor turnover, accidents and absenteeism. This appears to make the psychiatrist and allied personnel members of management and raises suspicion in many unions who fail to see that better mental health has as a by-product increased production. Some would say that the answer is for unions to undertake this responsibility, but few unions have done so, and many argue that this should be a joint responsibility of union and management similar to many of the health and welfare funds now in existence.[58]

Industrial psychiatry will and should undoubtedly play a larger role in future mental health programs since it is no longer a question as to whether someone will deal with the emotional problems of workers, and collective bargaining will settle problems in this area as with other labor-management problems. The many problems in industry with emotional overtones include absenteeism and turnover, accidents and their sequelae, alcoholism, disability, motivation and rehabilitation, problems of promotion or lack of it, fatigue and impaired work output, occupational dermatoses, psychophysiological reactions, reaction to new employees or shifts within the company, besides the people with psychiatric problems that one industrial psychiatrist estimates to be at least a quarter of the working force.[59] The fruitfulness of mental health programs in this area is apparent. Special areas in which mental health programs may be undertaken, along lines mentioned previously, are premarital counselling, counselling in cases of threatened separation or divorce, and advice to parents on adoption. Whether such programs actually prevent neuroses or promote better family life for the children and involved parties has never been adequately demonstrated although current tension situations may be relieved. With medical advances of the past few decades problems are arising not only in the rehabilitation of people with some physical disability but also in regards to their emotional adjustment. Thus, the cardiac patient, young or old, must make certain adaptations or suffer because of it, and it is in these adaptations that the patient may fail. A child with a cardiac condition may easily develop without the give and

take of childhood necessary for personality growth, and this is often aided and abetted by parents and relatives who have received inadequate advice in this regard from physicians. The adjustment of the hard-driving, middle-aged man following a coronary is another fertile area where emotional frustrations and disappointments can lead to a self-pitying, unproductive life that can be prevented by proper techniques of rehabilitation, physically and emotionally. Another chronic condition with many psychic overtones is tuberculosis even if the controversy about emotional factors leading to a relapse is ignored. The imposed dependency and long hospitalization required often produce many problems in mental health. It is believed that 40 to 60 per cent of discharges from tuberculosis hospitals are against medical advice, and much of the responsibility for this is due to the inadequate medical care given the whole person with neglect of personality and environmental problems. There are also patients who fail to adjust following discharge, or who have relapses shortly after discharge. The need for improved occupational and educational therapy with better social work and psychiatric consultation could go far in averting many of these mental problems. The emotional reaction to the diagnosis of cancer and other fatal diseases and the follow-up after treatment can be very severe. This is a subject upon which very little has been written, and much work is needed as many of these patients may live for years, and efforts should be made to keep them as productive and free of emotional symptoms as possible, not only for their own sake but for those that must live with them. Certain problems that come up and must be dealt with are feelings of having never fulfilled oneself, guilt feelings towards intimates and the fear of losing control over oneself.[60]

During the past decade there have been mutual efforts on the part of organized religion and other groups concerned with mental health for a reapproachment. It would appear self-evident that the concern of the church is for the mental health of its members, and its influence is not merely restricted to church members but through its affiliated institutions, educational and medical, the opportunities for promoting mental health are widespread. The church may provide an outlet for creativeness, and many of its activities may do much to help the aged adjust. Through the expanded role of the clergyman as a counselor, he is performing a psychotherapeutic function besides selecting those individuals who should get medical help. The church also offers consolation in case of death, sickness, disaster and atonement for those guilty of transgressions. These are the potentialities of the church for preventing mental illness and needless to say, like all the other activities previously mentioned, the success depends on the individuals involved and how they use these instrumentalities. Religion does have theoretical differences from the scientific approach by maintaining some factor of unassailability, a feature that depends upon belief and faith in the possibility that physical laws can be temporarily revoked by supernatural intervention. But there is a similarity in the ideals and goals of religion and the mental health sciences even though the ideologies may superficially seem to clash, and insofar as the final goal is to permit an individual to realize himself in the most productive relationships with others, there should be no conflict.[61]

There still remains a group of very controversial measures in respect to the prevention of mental illness that should be mentioned. The first is the belief that much mental illness is due to the expectation the individual has for the future and not just his past experiences, and programs of social, economic and political reform to promote the overall mental health in a community are primary to any comprehensive advancement. Those who champion this position say that stress should be laid on preventing many disastrous family crises, such as unemployment, inducting the head of a family into military service, et cetera. It is believed that a satisfactory social adjustment is not possible under demoralizing circumstances from which a resolution is not foreseen. Various types of social legislation have been enacted whose underlying assumption must be that the prevention of much mental illness can be done via modifications of existing laws. Thus, unemployment compensation ("the sense of security following the loss of a job"), old-age and survivors insurance ("security from loss of income from old age, disability and death"), maternal and child health and welfare services (the Children's Bureau that administers grants to states to promote the health and welfare of children), vocational rehabilitation (to restore the ability of not only physically handicapped but patients with emotional disturbances and dischargees from mental hospitals), and the public health service with its wide public service

functions and since the National Mental Health Act of 1946 the National Institutes of Mental Health for research and community services.[62] The broad social implications of these measures will not be discussed here except to say that such approaches have not been tested epidemiologically but are a part of the social climate of our century that believes in and wants such activities. A second proposal sometimes heard is for eugenic sterilization of the mentally ill, and again the evidence to justify such a procedure is lacking. Although there is much evidence suggesting a hereditary nature for mental illness, the exact relations are not yet determined, and such a program would eliminate many gifted individuals besides depriving them of personal liberty. A third measure is preventive analysis, the use of psychoanalysis for individuals not yet ill but who are thought to have a high chance of becoming ill. Besides the arguments given previously against the effectiveness of analysis as a general measure, it is not now capable to predict with a high level of accuracy who will become ill, or what would happen without analysis. Although on an individual level, this program might be very useful. If our level of predictability increased, some type of preventive psychotherapy would undoubtedly be beneficial. The selection of key groups and ages presented here is not exhaustive, but it is believed this covers the major areas under consideration at the present time and that any exclusion of these groups in a program will leave a serious deficit.

V

After this review of mental health problems, the myriad numbers of people on whom the success of a program depends is seen—parents, families, teachers, religious leaders, recreational workers, physicians and nurses, all of the professions, and those who direct governmental and industrial organizations. From this ubiquitousness, the widespread concern about social health has developed, for the above groups include all problems of "social health" from intra-familial difficulties to labor-management disputes to international crises. Despite whatever psychological "dogma" one may adhere to, mental illness encompasses social and environmental forces, as well as organic and intrapsychic disturbances. Many now hold that we must have a change in our basic social philosophy to meet the mental health problems in our modern complex world. It is believed that while applied science has brought about wide changes in our mode of living, large numbers of people are guided by the same standards and attitudes that provided security in an earlier age but are no longer effective to deal with the complex problems of today. Anthropological and psychiatric research has shaken one of the long entrenched beliefs that our social ills come solely from individual conduct that must be corrected and punished, so that the supposed underlying social forces can operate without hindrance and thereby solve our problems; the social forces and laws are found to be merely specific historic creations of people and not inherent, immutable powers in group life. There is the possibility of reconstructing our culture and creating a more satisfactory emotional climate in which age-old frustrations and deprivations may be mitigated if not eliminated.[63] To accomplish this requires strong democratic leaders who see the effects that behavior in one part of society has on the other, and who have an understanding of individuals and groups. Such leaders, in government, industry, the professions, in religion and in education must be dissatisfied enough with current progress being made in preventing behavior disorders that they are willing to spend much of their time and effort in promoting research for new knowledge about behavior, furthering public health programs that we now have to successfully combat mental illness, and maintaining their devotion to hold to their course while a healthier society is slowly constructed. It is no longer possible to evade responsibility for the prevention of mental illness as "no known man or body of men now has the power to arrest the flow or alter the general direction of events, even if, on mental health grounds, that should be indicated. If we, the mental hygienists, should amputate our writing arms and seal our reluctant lips, the field would fall to the quack and charlatan, and the principal difference would be that the self-consciousness would be worse founded and more misleading. There is no choice open in that direction for us, any more than there is a way of abdication for the physicists in the face of the atomic bomb and its more violent variants."[64]

If one may go beyond the objectives of the present in merely trying to "hold the line" and just prevent the occurrence of mental illness, there may come a time when psychiatric and public health efforts will be directed toward having an individual achieve the peak effectiveness to which he is capable. It will be a cause for concern not only to

deal with one's deviations but also with one's assets, and we will worry about all those who fail to live up to their capacities, who have healthy bodies but do not use them to their own satisfaction, who are admirably equipped for physiological survival but who do not achieve psychological vitality. These are the 70,000,000 or more Americans who may not be living up to their best psychological stuff with much ineffective worry and anxiety and not handling their vocational, marital or child-raising problems.[65] If this paper could be concluded with some generalizations, it could be said that a successful solution to present and future mental health problems will draw from natural science and related social sciences, from anthropology and from organized religion. It will embody a program that gives purpose and meaning to each man's life, allays his fears and distrust, and induces and maintains such mutual confidence, co-operation and support as are needed for living together in families, groups, societies and nations.[66]

Lateral Ventral or Spiegel's Hernia

T. J. MILLER, M.D.
R. H. LA BREE, M.D.
Duluth, Minnesota

From St. Mary's Hospital, Duluth, Minnesota, and the Department of Surgery, The Duluth Clinic, Duluth, Minnesota.

GENERALLY speaking, external anterior abdominal wall hernias are commonplace and offer no great problem in diagnosis and differentation. Inguinal, umbilical, femoral and incisional defects constitute over 98 per cent of all anterior abdominal wall hernias, the first three types occurring through natural apertures provided for the emergence of important blood vessels and other structures, such as the spermatic cord and the round ligaments of the uterus.

By far less readily explained and diagnosed, lateral ventral or Spigelian hernia is rare. Infrequently considered in the differential diagnosis of abdominal pain, these unusual defects may simulate a variety of pathologic conditions.

These hernias may occur anywhere along the linea semilunaris (Spiegel's line) which extends from the ninth costal cartilage to the pubic spine. This line lies along the outer border of the rectus abdominis muscle and corresponds to the aponeurosis of the internal oblique, between its division to form the rectus sheath medially and the termination of the muscle laterally.[1] The hernias are most frequently seen near the linea semicircularis (the so-called fold of Douglas). Those hernias occurring below the inferior epigastric artery are generally not considered to be Spigelian in type.

Various theories have been put forth to explain the cause of these defects. Several structural characteristics of the anterior abdominal wall are thought to contribute to the development of these hernias. Bailey[2] found that the muscular portions of the internal oblique and transversus abdominis consist of separate musculo-aponeurotic bands, rather than strata of evenly divided fascicles. In 10 per cent of abdominal walls, Bailey demonstrated that the defects between these bands were superimposed and were common near the linea semicircularis. Mersheimer et al[3] emphasized the fact that the fibers of the aponeurosis of the internal oblique and the transversus abdominis traverse at definite angles to each other above the umbilicus but are nearly parallel below it. Defects in the transversus abdominis along the lateral margin of the rectus muscle have been observed. These defects are thought to be relative to the lateral perforating branches of their inferior epigastric artery. Moschowitz[9] accepts Cloquet's lipoma theory as the best explanation for the development of lateral ventral hernias. The outgrowth, or protrusion, of a properitoneal lipoma through the fascial hiatus alongside a small vessel may later drag a funnel of peritoneum after it forming a true hernial sac. Since man's posture is erect, the pelvis tilts forward subjecting the lower abdominal wall to abnormal strains and pressures.

In its development, such a hernial sac penetrates the transversalis fascia, the transversus abdominis muscle and the internal oblique aponeurosis. Thus the hernia remains deep to the external oblique aponeurosis and may dissect beneath it. The sac contents are usually omentum, small intestine or large intestine, but the appendix and ovary have been found in it.

Predisposing factors in the development of these hernias include obesity, chronic cough, severe or repeated muscular effort and pregnancy. Several cases have been associated with varicose veins and other hernias.

Clinically the patient usually presents complaining of a mass, abdominal pain, or both. Often the pain is localized to the hernia site but may be of varied quality and related to body position. Occasionally these patients have presented with symp-

toms simulating acute appendicitis.[5,6] Small bowel obstruction has also been observed.[7]

On physical examination, the mass is often not readily demonstrated, presumably due to its position deep to the external oblique aponeurosis. One is more likely to make the diagnosis by examining the patient in the standing position, or by having the patient strain to sit up. At times a cough impulse or even the fascial defect may be palpable. If the latter findings are not present, it may be difficult to distinguish the mass from a tumor of the abdominal wall,[3,4] or from an intra-abdominal tumor.

Treatment of these rare hernias is surgical and consists of approaching the mass directly and separating, or incising, the external oblique aponeurosis. The hernial sac is then freed from its surrounding structures, a high ligation is done and the redundant portion of the sac is excised. Careful closure is then accomplished by layer approximation of the transversus abdominis or transversalis fascia, internal oblique, external oblique and skin.

Case Reports

Case 1.—This was a thirty-six-year-old white female, admitted to St. Mary's Hospital on August 20, 1959, complaining of a left lower quadrant mass of five years' duration. The mass had been gradually enlarging but was always reducible by the patient. This patient also complained of a dull ache in the area of the mass. This pain was aggravated by walking and was relieved by lying down. The patient denied any gastrointestinal or genitourinary complaints.

Past history revealed that the patient had a right inguinal hernia repaired about five years previously. The patient also had varicose veins of the lower extremities of twelve years' duration.

Physical examination revealed an obese, white female. General physical findings were within normal limits, except for varicosities of the lower extremities and the presence of a soft, non-tender mass, about 6 x 8 centimeters, palpable in the upper left inguinal area. This mass lay medial to the midpoint area between the anterior-superior spine and the umbilicus, was easily reducible, and was thought preoperatively to be an inguinal hernia, even though it was noted to be somewhat high.

At surgery an incision was made directly over the mass. The hernial sac was confined beneath the external oblique aponeurosis, and contained omentum. The hernial defect was at the linea semicircularis. Because of its size, it was necessary to imbricate the internal oblique aponeurosis with the underlying transversalis fascia to close the defect after ligation of the sac. The external oblique, subcutaneous tissue and skin were then approximated.

The patient was discharged on the sixth postoperative day after an uneventful recovery.

Case 2.—The second patient was a fifty-three-year-old white female first seen in St. Mary's Hospital on February 9, 1950, complaining of a mass in the right lower quadrant of seven years' duration. The patient described this mass as being about the size of a golf ball but although she had seen several physicians, the mass had not previously been found on physical examination. The mass was described as more prominent on standing. The patient admitted also a sharp pain in the area of the mass. This was at first constant. Later it became intermittent and disappeared with reclining.

The patient had also complained of a pulling sensation in the right upper quadrant not specifically related to food intake. There were no other gastrointestinal complaints. The patient admitted increased frequency of urination, nocturia one to three times a night, and occasional burning on urination during the past two years.

Physical examination revealed an obese patient. The abdomen was soft and non-tender. A small umbilical hernia was noted. In the right lower quadrant, a soft non-tender poorly defined mass was found; this was estimated to be about 4 x 6 centimeters in size.

The various diagnoses at that time were: Right kidney cyst; lipoma of the abdominal wall, or a tumor of the cecum. An intravenous pyelogram was normal. A barium enema demonstrated the cecum displaced upward apparently due to extra-colonic pressure. It was thought that the mass was extra-pelvic. The patient was discharged from the hospital and returned on March 2, 1950, for an exploratory operation.

On this second admission, the mass was noted to be somewhat tender and was more apparent on standing. The possibility of this being an abdominal wall hernia was suggested at this time.

At surgery, a right paramedian incision was made and the abdomen was explored. The abdomen was found to be intact except for the presence of a 3½ x 4 centimeter hernial defect in the right antero-lateral abdominal wall. A second incision was made directly over this defect. It was noted that the hernia had remained deep to the external oblique aponeurosis. The sac, which contained omentum, was ligated and excised. Repair was accomplished by layer closure of the transversalis fascia, internal oblique, external oblique, subcutaneous tissue and skin.

The patient was discharged after an uneventful recovery.

Summary

The etiology and clinical diagnosis of Spigelian hernia are briefly discussed. Two new cases are reported. It is suggested that patients with complaints including abdominal pain and the presence of a mass, especially along or near the linea semilunaris, always should have included in the physical examination palpation of the abdomen in the standing position. Only in this manner will many of these rare hernias be identified.

Herpes Zoster Treated with Prednisolone

ROBERT B. TUDOR, M.D.
Bismarck, North Dakota

From the Department of Pediatrics, Quain & Ramstad Clinic, Bismarck, North Dakota.

MANY UNFAVORABLE reactions have recently been reported in patients with herpes zoster and chickenpox who were receiving Cortisone.[1] Weller, employing complement-fixation and neutralization procedures, has observed no significant antigenic differences between the agents isolated from the two diseases.[2]

The subject of this case report is a child who was treated with Prednisolone for herpes zoster and eczema.

Case Report

A.G., aged seven years, has had severe atopic eczema since she was four. Scratch tests showed multiple sensitivities to foods, pollens and epidermals. She had been treated with all the usual topical medications recommended for this disease, including coal tar, oxyquinolone and hydrocortisone ointments. She had also been hyposensitized at weekly intervals, using pollens and epidermals to which her skin reacts. In spite of almost daily examinations, it was finally necessary to give one tablet containing 5.0 mgms. of prednisolone and 10 mgms. of hydroxyzine hydrochloride (Ataraxoid) three times daily at least four days a week to control her eczema.

On August 27, 1959 she was admitted to the St. Alexius Hospital because of an exacerbation of her eczema, complicated by multiple pustules. Cultures from the skin and anterior nose disclosed streptococcus viridans. Blood and urine studies revealed essentially normal values. Her temperature was normal. An aluminum acetate solution (1:40) was applied to the skin and she was given one Ataraxoid tablet and 200 mg. of erythromycin every six hours. She was discharged from the hospital on September 8 with fairly normal appearing skin except for the chronic lichenified lesions which are always present in her popliteal and cubital areas. The evening of her discharge a few red spots appeared on her right upper chest. She returned to my office on September 10 with an acutely weeping eczema and herpes zoster involving the anterior right chest wall, at the level of the fourth and fifth thoracic dermatomes. The zoster consisted of a cluster of vesiculobullous lesions and erythematous papules. There was no evidence that herpes generalisatus had occurred.[3] Her Ataraxoid tablets were again given every six hours and the skin was kept clean but no topical medications were applied. The herpetic lesions did not spread and were dry on the 12th. She was discharged on September 14. She was next seen on the 17th, when the eczema was well controlled and no evidence of the zoster could be seen.

Summary

A child with severe eczema and herpes zoster was treated with prednisolone, and no alarming complications appeared.

When herpes zoster is complicated by an illness which requires cortisone, it is felt that under well controlled conditions, no serious contraindication exists to its use.

CHRONIC LOCALIZED BRUCELLOSIS WITH RECURRENT CONSTITUTIONAL MANIFESTATIONS

Localized brucellosis refers to that variant of the disease wherein one can culture brucellar organisms from various tissues of the victim, such as the lung, spleen, and bone. In cases of this kind, the process often is relatively asymptomatic; detection of a localized lesion of the lung on a routine roentgenogram is a typical happening. Preoperatively the surgeon may be unaware of the nature of the lesion; hence his securing material is of extreme importance diagnostically. Rarely, localized brucellosis produces recurrent systemic manifestations for years prior to isolation of the organism from tissues. This unusual type of the disease may generate considerable confusion before definitive diagnosis is achieved, and it warrants consideration in cases of recurrent fever.

Sites of chronic localized brucellar infection associated with recurrent constitutional manifestations have been reported as including the gallbladder, liver, spleen, bone, lymph nodes, and an ovarian cyst. At the Mayo Clinic, the most common locus responsible for this syndrome has been the spleen. The symptomatic episodes usually occur yearly or more often, and ten years or more may pass before the process is identified. The episodes typically begin with a definite chill and continue with fever (oral temperature of 102° to 104° F.), sweats, malaise, myalgia, and headache, lasting two to seven days. Anorexia, nausea, and vomiting may be present; and abdominal pain, which may be related to splenomegaly, has occurred. Other symptoms and signs may be present, depending on the locus. In the experience at the Mayo Clinic, Brucella suis has been the organism most frequently responsible.

In contrast to serums from patients with bacteremic brucellosis, wherein agglutination titers exceeding 1:200 at some time during the illness are expected, in serums from patients with localized infection the agglutinins may be absent or appear only in low titer. Therefore, since cultures of the blood and serologic tests in this type of the disease may not be helpful, one's clinical suspicion of it must be correspondingly heightened if the diagnosis is to be made.

When the locus is in the spleen, thrombocytopenia and leukopenia apparently due to hypersplenism may alert one to the syndrome. Also, the clinical finding of splenomegaly may be corroborated roentgenographically by evidence of splenic calcification and of displacement of the gastrointestinal tract on barium-contrast studies.

It appears that antibiotic therapy alone is not capable of subduing chronic localized brucellar infections when the locus is in the spleen. Splenectomy definitely eliminates the splenic locus, provides cultural proof of the suspected disease, removes any hypersplenic effect on the marrow, and allows detection of additional brucellar lesions, such as retroperitoneal abscess, which have occurred in such cases.

A persistent question is whether antibiotic therapy should be given after surgical removal of the nidus. At the Mayo Clinic such therapy usually is recommended. There is mild controversy regarding the addition of streptomycin to tetracycline in treating brucellar infections; experience at the Mayo Clinic indicates such combined therapy to be more effective.

William J. Martin, M.D.

INDUSTRIAL HEALTH AND AIR POLLUTION IN MINNESOTA

One and one-half million people make up Minnesota's labor force. These are the people who are the family bread-winners, the people whose continued employment supports the economy of the state and the people who pay income taxes. Making jobs available for these people and keeping them on the job requires the dedicated effort of many groups and agencies.

"Industrial Health" programs place their emphasis on measuring, evaluating and controlling those environmental factors which may adversely affect the health of people in their places of employment. Volumes of information are available on the diagnostic establishment of the existence of

such traditional occupational diseases as silicosis, lead poisoning and benzol poisoning; on the conditions under which such diseases will occur; and on the engineering know-how for their control. Although the incidence and severity of these illnesses have been reduced, they are still with us.

Increased productivity is vital to our expanding economy. New materials, new methods, and new machines, while making this possible, eliminate some of the traditional hazards to health and improve working conditions, but simultaneously they may increase existing hazards and add a great many more to the working environment. Answers are presently being sought on the measurement of noise in industry and its effect on hearing, on the hazards of using radioisotopes, on new procedures like shielded-arc welding and on new materials such as high energy fuels or pesticide combinations.

The biggest problem facing industrial health workers today is not the establishment of the hazardous nature of a new material nor the evaluation of its use in a work situation nor the determination of means for its control, but getting recognition of the hazardous nature of materials or operations and getting adoption of good engineering control practices. Much of large industry with hazardous conditions has recognized the importance of employing staff members with industrial health training. Most people, however, work in establishments too small to employ professional health personnel. It is in these small firms that the greatest need for technical know-how exists.

Air pollution and industrial health problems are similar only in that air and its contamination are involved in each case. It can be expected that at some stage in industrial growth and population concentration problems of air pollution will occur in a community. This may be evidenced by smoke palls, reduced visibility, property deterioration, eye irritation, respiratory difficulties, or even increased morbidity and mortality rates.

An air pollution problem may exist in a community because a single source disperses an odor or black smoke or an irritating gas in a downwind direction so that there is a simple cause and effect relationship. A burning dump may be an obvious source of air pollution which needs community action for control. The elimination of such a source and perhaps several other major sources of air pollution may not greatly improve the overall problem. The general public collectively, traffic and industry may each be making a major, and, perhaps, equal contribution to the level of air pollution in a community.

In Minnesota we have been complacent about air pollution as a problem. We have been blessed with wide-open areas, with favorable topography, with fast moving meteorologic conditions, with high-grade fuel use and with absence of concentrated heavy industry. There is evidence, however, that continued complacency may not be justified.

Industrial health and air pollution programs both concern themselves with measurement, evaluation and control of air contamination. Engineering know-how is available for the solution of most industrial health problems but much basic information on environmental factors is needed before satisfactory solutions can be found for our air pollution problems. The air we breathe may well be one of Minnesota's most valuable resources. It is not too soon to be considering the need for air conservation measures.

F. L. Woodward

DRUGS IN THE TREATMENT OF OBESITY

Drugs and hormones have been given an endless trial in the treatment of obesity. Let us dispense with the use of hormones by saying that I have never read a report of a "double-blind control" study in which any hormone has helped. This statement includes the use of thyroid in any form, since extremely few obese persons are deficient in thyroid and since patients with true myxedema usually are not obese; the loss of weight in such patients is largely accounted for by water loss. No good evidence exists for the use of any other hormone from any other gland, such as the pituitary, pancreas, adrenals or gonads.

The use of some dangerous drugs has been eliminated. As an example, no one now prescribes alpha-dinitrophenol, which did produce weight loss but which also caused cataracts and sometimes death.

We are left, therefore, with a large number of drugs to depress the appetite. Millions of tablets and capsules of drugs of the amphetamine group have been prescribed, but only rarely have these drugs been submitted to double-blind control studies. However, the company producing phenmetrazine hydrochloride (preludin) has encouraged such studies, and the patients taking this

drug have done better than the controls. I have no doubt but that these medicaments do decrease the appetite, but only for a short period. To my knowledge, no one has published the results of a study employing double-blind controls at the end of one year, and I believe a safe prediction would be that no difference would be apparent after such a period. There would be no difference because the patients would not be different, and the same patients who turn to food for the relief of tension would be fat again. A few, whether receiving a drug or a placebo, would have reduced to a normal weight because they had solved the problems causing their increased appetite.

I am referring, of course, to ethical drugs prescribed by ethical physicians. The money spent by the public for weight-reduction drugs has stimulated the Committee on Government Operations to publish a report (August, 1958, #29394) entitled, "False and Misleading Advertising (Weight Reducing Remedies)." The Committee estimates that the public spends $100,000,000 annually on such products, and the Food and Drug Administration, the Post Office Department and the Federal Trade Commission are making a co-operative effort to protect the public "from being bilked through fraudulent advertising." They specifically mention Regimen (Drug Research Corporation), R.D.X. (Pharmaceuticals, Inc.), Ayds (Carlay Division, Campana Corp.) and Slim Mint (Thompson Medical Co., Inc.).

In addition to the worthless drugs that are advertised indiscriminately, the public also is enticed by a long list of amazing mechanical measures for weight reduction, such as vibrating machines and oscillating couches, used either in health salons or in the home, none of which are worth a tinker's dam.

Sooner rather than later, patients should be persuaded by their physicians to recognize that obesity is a symptom of a disturbance of "life" rather than anything physical. The patient should be told that just as there are a few patients who turn away from food (and acquire anorexia nervosa), there are millions who turn toward food. I am sure that more obese patients could be helped with good psychotherapy than with simple dietotherapy, but this is not a very helpful statement if it implies that all fat people should see psychiatrists; there are too many of the former for too few of the latter. This means that Dr. John Doe must be the first line of defense in the hope that he can prevent the need for formal psychotherapy. With "amateur" help from interested general practitioners, many patients can approach the problem honestly and, at the end of months or a year, be on the way to a solution. Some patients need "professional" psychotherapy; this aspect of obesity is thoroughly reviewed by Bruch.[1]

During this time, the question remains as to whether the physician should prescribe anorexigenic drugs. I sometimes do, but I always say, "This drug is not the answer to your problem, but it does help some people for a few weeks or months." Most of the time, I prefer to ask my patients to join with me in trying to get at the cause rather than at the symptom.

GOVERNOR'S CITIZENS COUNCIL ON AGING

Minnesota has been a vanguard among the states recognizing the responsibility of government for programming to meet the needs of older citizens. As early as 1951, a legislative interim commission was appointed to study these needs and methods for meeting them. Only New York and California preceded Minnesota's program. In 1957, thirty-seven states took similar action. By 1956, the reports of interim commissions indicated our state ranked among the top ten in percent of the total population who were over sixty-five years of age. Other findings pointed to the lack of opportunities for independence, self-reliance and meaningfulness to life for persons in this age group. Our social progress was not keeping abreast of medical progress.

The study of earlier commissions clearly indicated that not all of the problems could be or should be resolved by government. An advisory body was appointed by Governor Freeman to seek means for developing more meaningful roles and opportunities in later life. This group, the Governor's Citizens Council on Aging, is composed of twenty-six representatives of organizations throughout Minnesota that have a direct interest in the field of aging. Mrs. Althea Atwater, a retired social worker and former member of the School of Social Work staff, is chairman. Recently appointed

members of the medical profession are Dr. Leo A. Nash of St. Paul, chairman of the State Medical Association Committee on Aging, and Dr. Albert J. Greenberg of Minneapolis.

The Council meets monthly to conduct hearings on health, housing, welfare, employment, education, and leisure time programs. From these discussions and fact finding, they make recommendations to the legislature and various state departments for the improvement of services and opportunities. In addition, the Council sponsored three major action projects during 1958: A Centennial Pioneers Certificate to 2,500 citizens ninety years of age and older; a series of stories for local papers throughout the state called Senior Salutes depicting the satisfactory adjustments made by local citizens; and a Governor's Conference on Aging which drew 940 participants and was hailed as one of the best state conferences on aging held in this country to date.

Culmination of the past year's activity will take place in legislative halls. A five-point program has been accepted by Governor Freeman and full support of the administration will be given to seeking passage of the following bills.

1. Removal of the maximum on Old Age Assistance grants. In Minnesota, 48,314 persons now receive aid. The amount they receive is based upon individual needs. But maintenance needs in 12 per cent of the cases exceeds the present maximum of $71 per month. In addition, the maximum does not permit employment of such services as housekeeping, homemaker, foster home care which would eliminate many placements in boarding care and nursing homes. The Department of Public Welfare has estimated that removal of the present maximum would cost Minnesota approximately $800,000 per year. More important, however, is the ability it would give welfare authorities to pay for services actually needed rather than limit them because of an arbitrary maximum.

2. The State Department of Health has only two inspectors for 626 licensed medical facilities in Minnesota. The Council feels that the standards of care cannot be raised in nursing and boarding care homes unless this staff is increased to six. This would cost $28,500 per year—a modest sum for the benefits that would be realized.

3. The boom in construction of nursing home facilities has greatly relieved the pressure felt in 1957 when the Council recommended state grant-in-aid to counties for construction or rehabilitation of nursing homes on a matching dollar basis. The 857 beds built and 1,160 under construction is misleading, however. Many areas of the state had no additions and will not have because lending institutions are hesitant to invest in these areas. Hence, the Council recommended that $1,000,000 be made available for "distressed counties on a matching basis," to stimulate new construction and assure the availability of services where they are most needed.

4. Only counties now have the authority to bond themselves for construction of nursing homes and homes for the aged. Several communities have sought special legislation to do so. It seems democratic and advisable that any village or city be so authorized, subject to approval of plans by the State Department of Health.

5. Commitment of persons diagnosed as senile is up 8 per cent since 1952 and now 40 per cent of all first commitments are over age sixty-five. It is estimated that 50 per cent to 70 per cent of all commitments are made without an evaluation of the resources, family background and other social factors being available to the court of the hospital. The Council recommends that the present law permitting probate judges to request such pre-commitment studies by the county welfare board be made mandatory. The value of such information for protection of the individual and for treatment program design is obvious.

The Council has made other recommendations for improved and increased services to older citizens. They support the Department of Welfare's program to pay 80 per cent of the administrative cost for employing a specialist in community projects such as mental health, mentally retarded, the aged, et cetera.

In 1959, plans call for development of a health committee to study means of financing medical care costs for the aged and for developing a classification index for the licensing of nursing homes. In addition, the Governor has charged the Council with the responsibility of developing plans for Minnesota's contribution to the White House Conference on Aging to be held in January 1961. Little more can be scheduled, for the Council will continue its efforts to develop local Councils on Aging

to aid in the tremendous responsibility of identifying who our aged are, what are their needs, and how can they be met. Society is faced with a new social phenomena—an abundance of older citizens —which requires creative planning on a long range basis.

Bernard E. Nash
Governor's Citizens Council on Aging

CONSTRUCTION NEEDS OF MEDICAL SCHOOLS

In a recent survey by the Association of American Medical Colleges, seventy-eight fully developed four-year United States medical schools indicated a need for $757.2 million in construction funds between now and 1965 for the building of new teaching, research, hospital, outpatient, and administrative facilities, as well as for the remodeling and renovation of existing plants.

Exclusive of student dormitories, recreational areas, and other facilities not directly related to teaching programs, this estimated need for construction funds breaks down as follows: $306.3 million, hospital and orthopedic facilities; $261.2 million, educational facilities; $142.8 million, research facilities; $32.2 million, rehabilitation and remodeling facilities; and $14.7 million medical school administration facilities.

Association of American
Medical Colleges

The National Tuberculosis Association, organized in 1904, was the first voluntary organization formed by doctors and laymen to work together against a specific disease. Today it has constituent associations in every state and territory. Affiliated with these are associations organized on a county or city basis. Altogether, there are 2,700 voluntary tuberculosis associations joined in a common cause. Their registered trademark is the red double-barred cross.

* * *

Tests have shown that about a third of the United States population has been infected with tuberculosis. One out of twenty of these will probably develop the disease.

Last year alone, there were over 80,000 new cases of tuberculosis. Those were the ones that were found. Another 100,000 Americans have tuberculosis in active, infectious form and do not know it.

ACCURACY OF ROUTINE GALL-BLADDER AND BILE-DUCT STUDIES

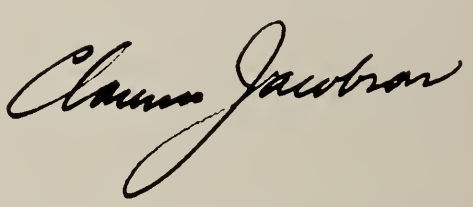
President's Letter

OUR WOMAN'S AUXILIARY



Members of the medical profession can state without contradiction that its Woman's Auxiliary continues to be its most effective ally. It is well to keep in mind that auxiliaries are not independent organizations, but parts of the American Medical Association and its constituent societies. This relationship enables the companion organization to become more intimately aware of the problems facing the medical profession.

Since its founding in 1922, the Woman's Auxiliary to the Minnesota State Medical Association has been and continues to be a dynamic group in carrying out its objectives. During the thirty-eight years of the Auxiliary, members have more than fulfilled these objectives when one surveys their activities. Auxiliary committees are working side by side with the State Medical Association, procuring funds for the American Medical Education Foundation, participation in the Civilian Defense, Community Service, Medical and Surgical Relief, Mental Health, paramedical careers and legislation, to mention a few. Many members of the nursing profession have, through encouragement and financial aid of the Auxiliary, been able to finish their training. When necessary, undesirable legislation for the public welfare is combated by letters to our legislators and congressmen from Auxiliary members.

The problem of the aging is being studied by the medical profession as a whole. We must recognize and must inform others that this is not a problem of the medical profession alone. Businessmen, community leaders, and civic groups must be educated to the point of view that sweeping national legislation is poor assurance for a high standard of medical care for these people. In this area also, we must be grateful for the efforts of Auxiliary members.

The members of the Auxiliary are well informed through their publication, the *National Bulletin,* and the Minnesota *Gopher Doctor's Wife.* The new *AMA News* has proven an effective publication for the Auxiliary as well. I know of no other auxiliary so well informed and willing to work for the ideals and objectives of the profession they represent.

Anything the State Association can contribute to our most worthy ally has been already amply repaid. Their loyalty and interest will continue to sustain us during the difficult years ahead.

President, *Minnesota State Medical Association*

Minnesota State Medical Association

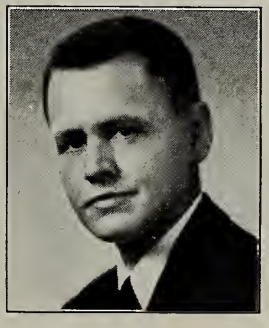
107th Annual Meeting

Rochester, Minnesota — May 23-25, 1960

Guest Speakers

KENNETH B. BABCOCK, M.D.

Chicago, Illinois



Kenneth B. Babcock, M.D., will participate in a Round Table Luncheon, Monday, May 23, at 12:15 p.m., on "Accreditation of Small Hospitals". Doctor Babcock is Director of the Joint Commission on Accreditation of Hospitals, Chicago, Illinois.

CLIFFORD J. BARBORKA, M.D.

Chicago, Illinois

"The Diagnosis of Gastrointestinal Cancer" will be the title of a presentation given by Doctor Barborka as part of the Symposium on Cancer Detection for Practicing Physicians, Tuesday, May 24 at 9:00 a.m. Doctor Barborka is Professor of Medicine, Chief of Gastrointestinal Clinics, and Director of Research in Gastroenterology, Northwestern University Medical School, Chicago, Illinois.

TAGUE C. CHISHOLM, M.D.

Minneapolis, Minnesota

Tague C. Chisholm, M.D., will present the Arthur H. Sanford Lecture in Clinical Pathology on Monday, May 23, at 11:30 a.m. Doctor Chisholm is Clinical Associate Professor of Surgery, University of Minnesota Medical School, Minneapolis, Minnesota. He is sponsored by the Minnesota Society of Clinical Pathologists.

GEORGE C. ESCHER, M.D.

New York, New York

"Chemotherapy" will be the title of the presentation to be given by Doctor Escher in the Symposium on Cancer Treatment on Tuesday, May 24, at 2:00 p.m. Doctor Escher is a Consultant, National Cancer Institute; Associate Sloan-Kettering Institute; and Assistant Professor of Medicine, Cornell University Medical College, New York, New York. Sponsored by the Minnesota Division of the American Cancer Society.

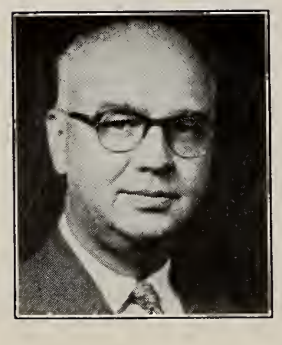
BENJAMIN FELSON, M.D.

Cincinnati, Ohio

Benjamin Felson, M.D., Professor and Director, Department of Radiology, University of Cincinnati College of Medicine; and Director, Department of Radiology, Cincinnati General Hospital, Cincinnati, Ohio, will present "Some Fundamentals of Chest Roentgenology" in a Symposium on "Diseases of the Lung" on Monday, May 23, at 2:00 p.m. Doctor Felson will also participate in a Clinical-Pathological Conference on Diseases of the Chest at 4:00 p.m. on Monday, May 23.

LAURENCE M. GOULD, Ph.D.

Northfield, Minnesota



Laurence M. Gould, Ph.D., will present the address at the Annual Banquet on Tuesday, May 24, at 7:00 p.m. Doctor Gould has chosen the topic "Education for A World of Change" for his address. Doctor Gould is President of Carleton College in Northfield, Minnesota.

WILLIAM J. GROVE, M.D.

Chicago, Illinois

A Symposium on Cancer Treatment on Tuesday, May 24, at 2:00 p.m. will include a presentation "Surgical Aspects" by William J. Grove, M.D., Chicago, Illinois. Doctor Grove, who is an Associate Professor of Surgery at the University of Illinois, Chicago, will also serve as Moderator for a panel on Management of The Far-Advanced Cancer Patient at 4:00 p.m. on Tuesday, May 24.

FREDERICK J. HOFMEISTER, M.D.

Milwaukee, Wisconsin

Frederick J. Hofmeister, M.D., will head a Round Table Luncheon on "Office Gynecology—Complete Gynecological Examination" on Monday, May 23, at 12:15 p.m. Doctor Hofmeister is the Director, Department of Obstetrics and Gynecology, Milwaukee Hospital and Marquette University. His appearance is sponsored by the Minnesota Department of Health.

JOHN S. LUNDY, M.D.

Chicago, Illinois

John S. Lundy, M.D., Consultant in Anesthesiology to Veterans Administration Research Hospital, and Associate Professor Surgery (Anesthesiology), Northwestern University Medical School, Chicago, Illinois, will present "New Means for the Safe and Effective Relief of Pain" in a Symposium on Management of the Far-Advanced Cancer Patient, Tuesday, May 24, at 4:00 p.m.

WAYNE E. MATHY, M.D.

Chicago, Illinois

"Prevalence of Rheumatic Fever in Minnesota" is the title of the presentation to be given by Wayne E. Mathy, M.D., in a Symposium on Rheumatic Heart Disease on Monday, May 23, at 9:00 a.m. Doctor Mathy is a Research Fellow in Infectious Diseases, Cook County Hospital, Chicago, Illinois. He is sponsored by the Minnesota Heart Association.

WALTER T. MURPHY, M.D.

Buffalo, New York

Walter T. Murphy, M.D., Director of Therapeutic Radiology, Roswell Park Memorial Institute, Buffalo, New York, will present the Russell D. Carman Memorial Lecture, Tuesday, May 24, at 11:30 a.m. The title of the Lecture is "The Meaning of Curative and Palliative Radiation Therapy". Doctor Murphy will also present "Radiation Therapy" in a Symposium on Cancer Treatment at 2:00 p.m. Tuesday, May 24. Doctor Murphy is sponsored by the Minnesota Radiological Society.

JOSEPH H. OGURA, M.D.

St. Louis, Missouri

Joseph H. Ogura, M.D., will present the Minnesota Academy of Ophthalmology and Otolaryngology Lecture at 11:00 a.m. on Tuesday, May 24. The title of his address will be "Cancer of the Throat". Doctor Ogura, who is sponsored by the Minnesota Academy of Ophthalmology and Otolaryngology, is Professor of Otolaryngology at the Washington University School of Medicine, St. Louis, Missouri.

BEN M. PECKHAM, M.D.

Madison, Wisconsin

"Tissue Diagnosis in Uterine Cancer" will be the title of a paper presented in a Symposium on Cancer Detection for Practicing Physicians, Tuesday, May 24, at 9:00 a.m., by Ben M. Peckham, M.D. Doctor Peckham is Professor and Chairman, Department of Gynecology and Obstetrics, University of Wisconsin Medical School, and University Hospitals, Madison, Wisconsin; and is sponsored by the Northern Minnesota Medical Association.

CHARLES H. RAMMELKAMP, JR., M.D.

Cleveland, Ohio

The Minnesota Heart Association is sponsoring Charles H. Rammelkamp, Jr., M.D., Professor of Medicine and Associate Professor of Preventive Medicine, Western Reserve University School of Medicine; and Director of Medicine, Cleveland Metropolitan General Hospital, to present "Treatment of Acute Rheumatic Fever" on the Symposium on Rheumatic Heart Disease, Monday, May 23, at 9:00 a.m.

ANTHONY RUPPERSBURG, JR., M.D.

Columbus, Ohio

Anthony Ruppersburg, Jr., M.D., will give a demonstration on "Maternal and Infant Mortality As Related to Obstetrical Mechanisms" on Tuesday, May 24, between 3:15 and 4:00 p.m. He will also head a Round Table Luncheon on Tuesday, May 24, at 12:15 p.m. on "Obstetrical Emergencies". Doctor Ruppersburg is Clinical Assistant Professor, Obstetrics and Gynecology, Ohio State University College of Medicine, Columbus, Ohio. He is sponsored by the Minnesota Department of Health.

A. H. SCHWICHTENBERG, M.D.

Albuquerque, New Mexico

A. H. Schwichtenberg, M.D., Head of the Department of Aerospace Medicine, The Lovelace Foundation for Medical Education and Research in Albuquerque, New Mexico, will present a Lecture on Space Medicine at 11:00 a.m., Monday, May 23.

HOWARD S. VAN ORDSTRAND, M.D.

Cleveland, Ohio

Howard Van Ordstrand, M.D., will be a participant in a Clinical-Pathological Conference on Diseases of the Chest at 4:00 p.m., Monday, May 23, in addition to his presentation of "Emphysema" on the Symposium on Diseases of the Lung at 2:00 p.m., Monday, May 23. Doctor Van Ordstrand is Head of the Department of Pulmonary Diseases at the Cleveland Clinic Foundation, Cleveland, Ohio.

Sports Events

Sunday, May 22

General Information

Participants in sports events, their wives, and all who attend the Annual Meeting are invited to attend a Sports Events Smorgasbord at 5:00 p.m. at the Rochester Country Club on Highway 14, south side of the road, three miles west of Rochester. Tickets for the smorgasbord, $2.75, gratuity included. Entertainment for doctors' wives who do not want to play golf will be provided at the Country Club.

Golf Tournament

Place: Rochester Country Club

Tee-off Time: 10:00 a.m.-12:00 Noon — Sunday

Prizes will be awarded to the low scorers. Green fees — $5.00. Make reservations individually or with your partner, indicating preferred tee-off time.

Skeet and Trap Events

Place: Rochester Gun Club

Time: 1:00 p.m.-4:00 p.m. — Sunday

The Club is located one-fourth mile west of St. Mary's Hospital on Highway 14 behind the golf driving range on the north side of the highway. Driveway entrance is behind State Highway Department offices.

Events will include regular skeet and trap rounds of twenty-five shots in each round. Prizes will be awarded at the Sports Events Smorgasbord at the Rochester Country Club.

George Earl, M.D., Chairman

THE FOURTH ESTATE COMMENTS ON SOCIAL SECURITY EXPANSION

Interesting are the editorial comments of the nation's press in light of the various proposals for expansion of the Social Security system to include medical care for the aged.

Among the many editorial expressions which questions the wisdom of such legislation are the following:

Social Security Is Increasing Beyond Defense

American taxpayers are presently committed to expenditures of over $1 trillion. One-fourth of the total, or upwards of $250 billion, is marked for payment of present Social Security obligations, Ardell T. Everett, Prudential Vice President, told the National Taxpayers Conference.

"The fastest growing item in federal spending is not defense but social welfare programs, which have been increasing at a rate of over $1 billion a year since 1953," Mr. Everett declared.

Federal welfare spending will amount to more than $20 billion during the next fiscal year, he said. "For the year ending June 30, 1958, special welfare expenditures at all levels of government amounted to $44 billion, 10 per cent of the national output."

The speaker contended that although Social Security taxes are called "contributions" they are "nothing more than another part of our total tax load."

"Our system of hidden taxes on products and services and emphasis on dollar take home pay—with payment of taxes through withholding devices—misleads the public as to the true tax burden necessary to support social welfare payments." (*Eastern Underwriter,* February 19, 1960)

Why Your Paycheck Is Shrinking

Uncle Sam Now Takes Bigger Withholding Bite: If you are wondering why your paycheck doesn't seem to stretch as far today as it did a little while back, Uncle Sam has one answer for you. More of it is being withheld at source.

That is, the government is getting an increased amount of it in higher Social Security taxes.

And some of you may be finding more withheld because of rising charges for hospital and medical insurance. Some may find more withheld under company pension plans.

Those lucky enough to have received a pay raise recently will also note that a sizable chunk of the increase is withheld at source to take care of federal income taxes, and in some cases state income taxes.

Even if your take-home pay hasn't dwindled because of this, there has been a steady if slow rise in the last year in the prices of many things you buy—except for that big item, food.

In most cases there has been an even larger rise in the cost of the various services you need or demand—all the way from transportation fares to fees for personal care.

The take-home pay shrinkage shouldn't have come as a shock to you. It was widely publicized ahead of time.

But the slimmer look of the paycheck figures gives many a person a start, nevertheless.

The Department of Commerce notes that in January the total of wages and salaries advanced to an annual rate of $276.5 billion.

The gain over December was more than $2 billion. And it put this January ahead of a year ago by some $28 billion at an annual rate.

But here comes the joker. In January, the Social Security tax rate rose to three per cent from 2 1/2 per cent. The government took in some $90 million more from employes (and a similar amount from employers).

Contributions are now running at an annual rate of $9.5 billion up more than $1 billion from the December rate. The Social Security tax rate will continue to rise to provide for increased payments. Part of these payments will be in larger benefits to the eligible—although not all over sixty-five are now eligible by any means.

But more of the increase in funds will be needed simply because there will be a lot more persons of sixty-five or over in the years ahead—and an increasing percentage of them will be eligible for benefits.

There are now some 15.5 million Americans in

this age group. It is estimated that by 1970 there will be 19 million and by 1975 nearly 21 million. Their percentage of total population continues to grow. The other big increase is in the number of those under twenty.

Those in the middle span remain much more constant. And it is this working group whose taxes are going up. In time the accumulated funds will be taking care of them, too, if only meeting part of their retirement needs.

Social Security payments aren't the only income of the older population by any means.

The Department of Health, Education and Welfare estimates that their total income has gone up $6 billion since 1954 to a total of $30 billion, with Social Security providing about $9 billion of it. Gains in private pension plans, employment, savings, investments and public aid make up the rest. (*Chicago Daily News,* February 19, 1960).

Report Hits U. S. Aid To Aged

The Republican minority of the Senate subcommittee on problems of the aged has submitted a report opposing federal aid recommended for elderly persons by the Democratic majority.

Senators Dirksen (Ill.) and Barry Goldwater (Ariz.) said there was no need for the federal government to interfere.

Warn on Taxation

"The children and middle-aged adults of today are just as ready to discharge their filial responsibilities as were those who preceded them," their minority report said.

"Our task is to give them the opportunity to do so without destroying their own standards of living by excessive taxation which must accompany unnecessary and ever larger government expenditures."

They opposed recommendations that the federal government finance health benefits for persons receiving old age and survivors' disability benefits. That plan makes no provision for the most needy of all, persons on public assistance rolls, the two senators said.

Charge Unfair Tax Load

The proposal to raise social security benefits would put an unfair tax burden on wage earners, they said, and ultimately would reduce America's power to advance living standards for everyone.

The Dirksen-Goldwater report objected to suggestions for new federal agencies to "establish a paternalistic control over our older citizens." Individuals and private firms have proven their ability to handle private pension plans, annuities and insurance, the report said, and if the federal government takes over the obligation, many persons no longer will try to meet their responsibilities. (*Chicago Sunday Tribune,* February 14, 1960).

Alert Politicians

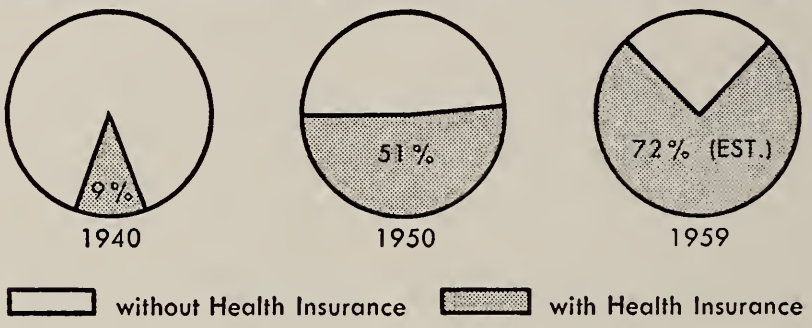
You have to hand it to the "liberal" politicians in Washington—they are certainly alert to new political possibilities. One of the newest to attract their cupidity is a rising proportion of older people in the population.

Thus a report just issued by a Senate Labor subcommittee headed by Senator McNamara urges a vast program of Federal aid to such people, to whom these politicians insist on applying the euphemism "senior citizens." There would be increased social security benefits, medical care as part of social security, public housing for the elderly, and even a Federal bond gimmick pegged to the cost of living.

Now no one questions that some older people have a hard time of it. What may very seriously be questioned is this notion that the way to help them is to make them a special group of mendicants along with farmers and healthy veterans and other categories on the handout list, and to do this for supposed political gain.

One of the chief difficulties older people have is caused by inflation. And pray what causes inflation? It is this wild Government spending, the fantastic deficits and debt with which "liberals" over the years have saddled the nation.

The way to help all the people, including old ones, is not still more reckless spending, deficit, debt and inflation. The right way is to halt this massive irresponsibility with the people's money by curbing spending and lowering taxes. And, if these politicians were only alert enough to grasp the point, that could also be the most astute politics. (Editorial, *Wall Street Journal*—February 9, 1960).



HEALTH INSURANCE PROTECTS 127 MILLION, ESTIMATED 1959 BENEFITS TOP $5 BILLION

An estimated 127 million Americans—three out of every four persons in the nation—were protected by health insurance against the cost of hospital and

doctor bills at the end of 1959. During the year, an estimated $5.1 billion in health insurance benefit payments were distributed among these insured persons by insurance companies, Blue Cross-Blue Shield, and other health care plans, according to the *Health Insurance News.*

Of the $5.1 billion in benefits, some $2.8 billion were paid out by insurance companies alone, up from $2.6 billion in 1958, the Institute declared. With the inclusion of benefits paid for accidental death and dismemberment, the insurance company total in 1959 reached $2.9 billion.

Percentage of U. S. Civilian Population with Health Insurance

Both the coverage and benefit figures were new highs. The 127 million insured persons, representing 72 per cent of the civilian population, surpassed the 1958 year-end figure of 123 million, and the $5.1 billion in benefits was an increase of 10 per cent over the 1958 sum of $4.7 billion.

The five major types of health insurance—hospital expense, surgical expense, regular medical, loss of income, and major medical—all showed an increase during 1959 in the number of persons protected, extending the consistent growth of health insurance.

In 1940, some twelve million persons, or nine per cent of the civilian population, were protected against the cost of ill health by health insurance said the Institute. In 1950, the coverage figure was nearly 77 million, or 51 per cent of the population, and in 1959 it was 127 million, or 72 per cent of the nation.

In 1959, the coverage increases were from 111 million to 119 million persons in surgical insurance, from 75 to 82 million in regular medical insurance, and from 42 to 43 million in loss-of-income.

Major Medical

The growth in coverage under major medical expense insurance, which provides benefits ranging from $5,000 to $15,000 to help pay for the cost of serious illness, was at a more rapid pace than the other types of insurance. The number of persons with major medical insurance rose 21 per cent, from 17 to 21 million.

The largest single outlay of benefit dollars by insurance companies was the more than $1.1 billion which went to defray the cost of hospital care, an increase of more than $70 million over the year before.

However, major medical expense insurance once again showed the greatest increase in benefits paid. Persons covered by major medical policies received an estimated $326 million in benefits in 1959, a 37 per cent increase over the 1958 figure of $238 million, and more than five times the 1956 total of $64 million. These major medical benefits pay for virtually all types of medical services, including medicines and drugs, medical appliances and physicians' services in addition to hospital and surgical care.

Surgical expense insurance accounted for $416 million in benefits, up from $402 in 1958, and persons with regular medical expense insurance policies received $106 million in benefits, up from $101 million.

Loss-of-income benefits rose from $850 million in 1958 to $912 million in 1959.

1959 BENEFIT PAYMENTS BY INSURANCE COMPANIES

Americans received an estimated $2.9 billion in health insurance benefits from insurance companies in 1959, an increase of nine per cent over the more than $2.6 billion paid out in 1958. A breakdown of benefits according to type of coverage for

the last two years, and the percentages of increase, follow:

Type of Coverage	*1959* (in millions	*1958* of dollars)	*Per Cent Increase*
Hospital Expense*	$1,139	$1,068	6.6%
Surgical Expense*	416	402	3.5
Regular Medical Expense	106	101	5.0
Major Medical Expense	326	238	37.0
Loss of Income†	912	850	7.3
TOTAL	$2,899	$2,659	9.0%

*Excludes benefits for hospital and surgical expenses received by major medical expense policyholders.

†Includes accidental death and dismemberment benefits.

DID YOU KNOW?

★ That before World War II, three out of every four hospital admissions involved surgery; today about three out of every five admissions involve surgery.

★ That three out of every ten persons involved in motor vehicle accidents require hospitalization.

★ That nearly one out of every seven Americans has a chronic or permanent health impairment.

★ That about six million Americans suffer from some degree of hearing loss, and visual defects of varying degree afflict three million Americans.

★ That a survey of dentists suggests that there is a higher incidence of tooth decay among women than among men.

★ That the average person in the United States sees his doctor five times a year, with most visits taking place at the physician's office; only 10 per cent of physicians' visits were to the patient's home.

STUDENT EXTERNS IN HOSPITALS NOT AFFILIATED WITH MEDICAL SCHOOLS

From a recent questionnaire of the Liaison Committee on Medical Education, information was obtained on the number of medical students throughout thirty-eight schools who were employed as externs in hospitals not affiliated with medical schools: 1.7 per cent of the sophomore students; 8.5 per cent of the junior students, and 14.2 per cent of the senior students were so employed during the 1957-58 academic year.

Public Health

LOCATION OF REGIONAL POISON INFORMATION CENTERS

Regional Poison Information Centers in Minnesota are located to provide service to physicians and hospitals by multi-county areas as follows:

POISON CENTERS

Hennepin, Scott, Sibley, Carver, McLeod, Wright
Abbott Hospital, FE 5-4201
Fairview Hospital, FE 6-6691
Minneapolis General Hospital, FE 3-1178
North Memorial Hospital, JU 8-2753
Northwestern Hospital, FE 2-7266

Ramsey, Dakota, Washington, Anoka, Chisago
Ancker Hospital, CA 2-7341
Bethesda Hospital, CA 4-7561
Children's Hospital, CA 7-6521
St. John's Hospital, PR 1-5521
St. Joseph's Hospital, CA 2-6321
St. Luke's Hospital, CA 2-6644

Blue Earth, Freeborn, Waseca, Faribault, Martin, Watonwan, Brown, Nicollet, Le Sueur
Immanuel Hospital—Mankato, Mankato 8-1605

Nobles, Rock, Pipestone, Murray, Cottonwood, Jackson
Worthington Municipal Hospital, Worthington 2-5601

Ottertail, Becker, Clay, Wilkin, Grant, Douglas, Wadena, Norman, Mahnomen
Lake Region Hospital—Fergus Falls, Fergus Falls 523

St. Louis, Lake, Cook, Carlton, Pine, Itasca
St. Luke's Hospital—Duluth, RA 7-6636
Virginia Muncipal Hospital—Virginia, HA 1-3340

Kittson, Roseau, Marshall, Polk, Pennington, Red Lake
Bethesda Hospital—Crookston, AT 1-4682
St. Francis Hospital—Crookston, AT 1-2490

Lake-of-the-Woods, Koochiching, Beltrami, Clearwater, Hubbard
Bemidji Hospital—Bemidji, PL 1-5430

Cass, Crow Wing, Aitkin, Todd, Morrison
St. Joseph's Hospital—Brainerd, Brainerd 2861

Stearns, Benton, Mille Lacs, Kanabec, Isanti, Sherburne
St. Cloud Hospital—St. Cloud, BL 1-2700

Chippewa, Kandiyohi, Meeker, Renville
Rice Memorial Hospital—Willmar, BE 5-4543

WHY THE DOCTOR IS OUT

The opening paragraph of the President's Letter by Doctor Clarence Jacobson, published in the April issue of MINNESOTA MEDICINE, was as follows.

DOCTOR IS OUT

He is attending the 107th Annual Meeting of the Minnesota State Medical Association where he is hearing scientific lectures by the leading scientists of the nation and viewing the latest medical and surgical techniques and equipment, that he may better serve your medical needs

The Doctor is expected back in his office (hour).

This message, prepared in printed form, has been enclosed with the 1960 Annual Meeting program. Members are urged to post this explanation in a prominent place in their office during their absence to attend the Annual Meeting of the Minnesota State Medical Association, May 23, 24 and 25, 1960, in Rochester.

EFFECTIVE PR

Focusing on several areas where the public image of the medical profession needs polishing, AMA Director of Communications Leo E. Brown—in a recent speech before the Michigan Academy of General Practice—touched on some basic ingredients of effective public relations that bear repeating. "Good deeds and their proper interpretation," he underlined as "the fundamental precepts of effective public relations . . . If you haven't done anything there is no story to tell. On the other hand, if you refuse to tell your story you cannot expect to receive credit for it," he explained.

His recommendations for improving the doctor image in three major areas of public dissatisfaction—namely, service, communications and finances: "The individual physician . . . has a very real obligation to the profession to do all within his power to maintain high quality service, to take the time to discuss with the patient his physiological well being, and to impress upon him his sincere interest, plus a frank discussion of the cost involved." As for the profession as a whole, Brown diagnosed the problem as one of negative approach—"Effective medical public relations can no longer be viewed solely as a preventive or holding operation but as a creative, organized activity to strengthen the future of medicine."

IS THE FIELD ALSO RIPE UNTO HARVEST HERE?

Physicians in the State of Idaho, recognizing that their profession is one of the last outposts of private enterprise and independence, have organized Idahoans for Good Government and are enlisting membership of the medical profession of that State.

Aims and functions of the organization are as follows:

—To help elect persons sincerely interested in preserving private enterprise (whatever their political party).

—To purchase advertising in all news media.

—To tell Idahoans that their family physician has been forced to become politically active to preserve the American way of life.

—To seek the support of all thinking Idahoans in this campaign.

Governed by an advisory board made up of physicians representing each component medical society in the State, Idahoans for Good Government will promote its programs with a small budget furnished by MD contributions. An outline of the committee premises stresses that doctors must be:

—Active members in political parties of their choice.

—Willing to spend money to fight for freedom and independence from further governmental interference.

—Willing to tell patients, friends and others why this fight is necessary.

A recent Minnesota Poll has indicated that 55 per cent of this state's population approves of the idea of providing health and medical care as part of the Social Security care for senior citizens.

Perhaps a similar organization in our State using comparable methods could help to inform Minnesotans regarding the high quality of medical care which they already enjoy.

MEDICAL EDUCATION AIDS LISTED

A program to attract talented high school and college students to the study of medicine has been outlined by the American Medical Association and the Association of American Medical Colleges.

The program points out that because medical school is many years ahead of the high school student, an aspiring medical student should concentrate on getting a broad, liberal education in his pre-medical school studies. Medical schools and the medical profession could do a service to high school faculty advisers and vocational guidance counsellors by making known the fact that vacancies do and will exist in U. S. medical schools. Medical careers informational media would help the high school counsellors by making the opportunities and rewards of medicine better known to their students.

Proper Pre-Medical Courses Important

The well-prepared and qualified students will be accepted into medical school. However, the student should learn the admissions requirements of specific schools so that he will follow the prescribed basic curriculum. An increase in the needs for more students in the future may be expected because of increasing population and the variety of careers being developed through medical progress—in research, teaching, practice and administration.

Because of the increased competition from other professions for the talented students, programs are being developed by AMA and AAMC to stimulate these students toward medicine.

Recruitment Aids Available

Services now available to state and county medical societies and medical schools to highlight the opportunities in medicine include the following new materials: (1) a 25-minute 16 mm color and sound motion picture entitled "I Am A Doctor"; a comprehensive handbook on "Medicine as A Career" for distribution to high school and college advisers containing a summary of high school, college, and medical school information to be used in counselling work; a brief pamphlet for wide-scale distribution to students, and a major exhibit on "Medicine . . . The Most Demanding Rewarding Profession" for showing at "career days," health fairs, and large community gatherings. These printed materials are available to medical societies and medical schools and the film and exhibit may be requested from the AMA or from your State Office.

ANTIDOTE FOR HIDDEN HAZARDS

A new booklet entitled "Hidden Hazards—the Unlabeled Poison Problem" by AMA's Committee on Toxicology has been mailed to chambers of commerce, poison control centers, communications media, farm and grange publications and other groups.

The American Medical Association is urging passage of federal legislation requiring precautionary labeling of all hazardous substances used in home and industry which are not now required by law to carry warnings.

The American Medical Association urges all state and county medical societies to launch educational programs based on this booklet as well as to inform congressmen of their official support of the bill. A special program-planning section has been inserted in copies going to medical societies to aid in planning these campaigns.

The first specific aldosterone-blocking agent...

ALDACTONE™

effectively extends the medical control of edema or ascites.

It introduces a new therapeutic principle in the treatment of...

CONGESTIVE HEART FAILURE • HEPATIC CIRRHOSIS
THE NEPHROTIC SYNDROME • IDIOPATHIC EDEMA

ALDACTONE introduces a new class of therapeutic agent, the aldosterone-blocking agent providing:

satisfactory relief of resistant or advanced edema even when all other agents, alone or in combination, are ineffective or are only partially effective.

A New Order of Therapeutic Activity

ALDACTONE acts by blocking the effect of aldosterone, the principal mineralocorticoid governing the reabsorption of sodium and water in the distal segment of the renal tubules.

By so doing Aldactone establishes a fundamentally new and effective approach to the control of edema or ascites, including edema resistant or unresponsive to conventional diuretic agents.

Further, because of its different site and mode of action in the renal tubules, Aldactone has a true, highly valuable synergistic activity when used with a mercurial or thiazide diuretic.

What Physicians May Expect of Aldactone

It is fully expected that Aldactone will change present medical concepts of the therapeutic limitations of managing edema. Many patients living in a greater or lesser state of edematous invalidism can now be edema-free. To others, gravely ill, Aldactone will be life-saving.

When used alone, Aldactone will produce a satisfactory diuresis in about half of those patients whose edema is resistant to conventional diuretic agents.

When Aldactone is used in a comprehensive therapeutic regimen, which includes a mercurial or a thiazide diuretic, a satisfactory diuresis and relief of edema may be expected in approximately 85 per cent of edematous patients *who would not otherwise respond.*

DOSAGE: For most adult patients the optimal dosage of Aldactone, brand of spironolactone, is 100 mg. four times daily. Aldactone should be administered for at least four or five days before appraising the initial response, since the onset of therapeutic effect is gradual when it is used alone. Aldactone manifests accelerated activity with greater response as early as the first and second days when used in combination with a mercurial or thiazide diuretic.

SUPPLIED: Aldactone is supplied as compression-coated yellow tablets of 100 mg.

Minnesota Blue Shield

SENIOR CITIZENS PLAN

Minnesota Blue Shield is currently enrolling subscribers in the Senior Citizens Plan, which provides medical-surgical coverage for persons sixty-five years of age and over. The enrollment period, May 1 through June 20, was scheduled to include both Mother's Day and Father's Day. Advertising messages suggest the Senior Citizens Plan as a Mother's or Father's Day gift.

This plan, which was introduced last October, provides benefits for 120 days of in-hospital medical care for each unrelated non-surgical illness during any twelve consecutive months; the full range of Blue Shield surgical benefits whether the surgery is performed in the hospital, the home, or in the doctor's office; electroshock therapy, x-ray treatment for specific conditions, and certain anesthesia services and endoscopic examinations. Also included are benefits for maximums of $50 of diagnostic x-ray services and $50 of laboratory services per subscriber in each period of twelve consecutive months, when such services are performed in the doctor's office, the patient's home, or in the out-patient department of a hospital.

No physical examination is required for Senior Citizen Plan applicants. There is a six months' waiting period, however, before benefits may be received for any pre-existing condition.

Applications for this Senior Citizens Plan will be accepted only during enrollment periods. The last enrollment period was conducted in October, 1959.

During this current enrollment period, a new plan for promoting non-group enrollment through drug stores is being tested. Folders describing rates and benefits, and including an application blank, will be made available in drug stores throughout the state.

The application blank, included in the folder, will be a postpaid card, addressed to Minnesota Blue Shield. As in the past, participating doctors will also be asked to offer the folders and application blanks in their waiting rooms.

A two-week program of radio messages will inform listeners that the applications are readily available at their local drug store or doctor's office.

The Minnesota State Pharmaceutical Association is cooperating with Minnesota Blue Shield, in asking pharmacists to place the folders in their drug stores.

In announcing the enrollment period, Dr. C. A. McKinlay, President of the Minnesota Blue Shield Board of Directors, said, "It is hoped that participating doctors will assume an active role in bringing the benefits of the Senior Citizens Plan to their patients who are sixty-five years of age or over. Members of the medical profession are deeply aware of the needs of patients in this age group, and recognize that low-cost coverage like that provided by the Senior Citizens Plan is a significant step toward meeting the pressure for government intervention in health care for older citizens."

Contracts will be effective on the first or fifteenth day of the month after receipt of completed application.

The cost of the Senior Citizen Plan is $2.95 per month for each subscriber payable quarterly.

* * *

Representatives of Minnesota Blue Shield are continuing to attend meetings of county medical societies throughout the state to report directly to doctors on the Blue Shield program.

Such reports have already been made to a number of societies, Dr. Richard R. Cranmer, Executive Director of Minnesota Blue Shield, said.

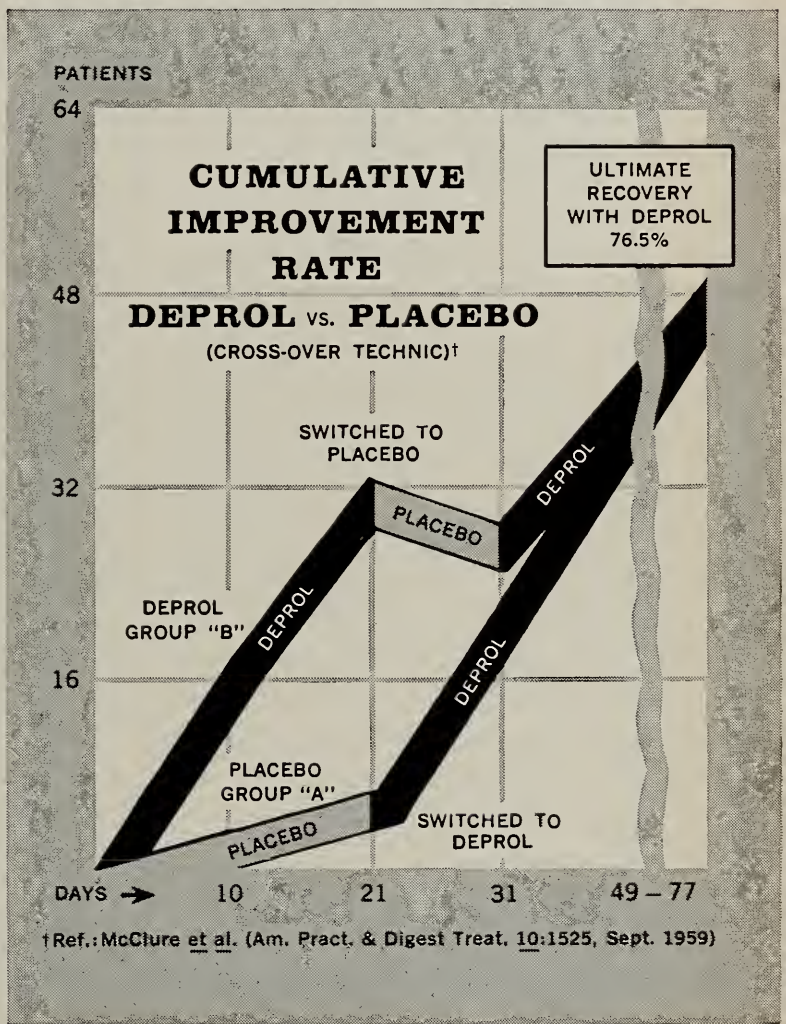
"We are hoping to have representatives appear before all of the societies in the state in the months to come," he said.

"The society meetings are affording an excellent opportunity to explain recent developments at Blue Shield, and answer any questions members may have."

"We welcome these opportunities to establish an even closer relationship with members of the medical profession."

A number of the county socities have adopted resolutions commending Minnesota Blue Shield on its program, particularly its introduction of benefits for diagnostic x-ray and laboratory services, when performed in the patient's home, doctor's office, or out-patient department of a hospital.

as it calms anxiety!



Smooth, balanced action lifts depression as it calms anxiety... rapidly and safely

Balances the mood – no "seesaw" effect of amphetamine-barbiturates and energizers. While amphetamines and energizers may stimulate the patient – *they often aggravate anxiety and tension.* And although amphetamine-barbiturate combinations may counteract excessive stimulation – *they often deepen depression.*

In contrast to such "seesaw" effects, Deprol lifts depression as it calms anxiety – both at the same time.

Acts swiftly – the patient often feels better, sleeps better, within two or three days. Unlike the delayed action of most other antidepressant drugs, which may take two to six weeks to bring results, Deprol relieves the patient quickly – often within two or three days.

Acts safely – no danger of liver damage. Deprol does not produce liver damage, hypotension, psychotic reactions or changes in sexual function – frequently reported with other antidepressant drugs.

TRENDS IN BLUE CROSS-BLUE SHIELD

The American Hospital Association is initiating an effort to weld all of the Blue Cross Plans into one American Blue Cross Plan. It is proposed that the AHA, AMA and the American Dental Association would work together in the development of this Blue Cross Plan. It is not clear as to what relationship would exist between this national Blue Cross Plan and the Blue Shield Plans. An article by Michael M. Davis, Ph.D., in the February 1960 issue of *Modern Hospital* suggests, however, that Blue Shield is a handicap to Blue Cross in its efforts to meet current demands for a larger scope of insurance services because Blue Shield will not face these demands with readiness and flexibility. It is suggested in this article that Blue Shield might be by-passed when it could not be persuaded to follow the Blue Cross lead, and it is also proposed that the hospitals be prepared to stand behind Blue Cross in an effort to include in one Blue Cross prepaid contract all x-ray and laboratory services, both inpatient and outpatient, as well as a still wider scope of physicians' services. It would seem that an effort is being made to develop a trend for a national Blue Cross Plan which would supplant all local Blue Cross Plans and which would take over in part, at least. present coverage offered by the Blue Shield Plans.

Frank C. Coleman, M.D.

FINANCIAL AID TO MEDICAL STUDENTS

One basic approach to the understanding of medical students' financial standing is to examine the facts concerning student indebtedness. Some recent findings concerning the experience of the 1959 graduating class are summarized below.

MEDICAL STUDENT FINANCES

1.	Number of Students in 1959 Graduating Class	6,799
2.	Average Cost of Four Years of Medical School to the Students in the 1959 Graduating Class	$ 11,642
3.	Estimated Total Cost of Four Years of Medical School to All Students of 1959 Graduating Class	$80,000,000
4.	Percent of Students in 1959 Graduating Class Who Have Liabilities From Any Source	52%
5.	Number of Students in 1959 Graduating Class Who Have Loan Liabilities Directly Related to Their Medical Education and Whose Total Liabilities are Greater Than Their Total Assets (Students Who Need Financial Assistance)	2,257
6.	Percent of Above Type of Students in 1959 Graduating Class	33%
7.	Total Liabilities of This Group of Students	$12,450,786
8.	Total Assets of This Group of Students	$ 2,841,716
9.	Total Indebtedness (Net Liability) of This Group of Students	$ 9,609,070
10.	Average Indebtedness (Net Liability) Per Student of This Group of Students	$ 4,258

A second factor bearing on the medical student's financial standing is his ability to pay for a medical education. This ability derives largely from the level of his father's income and the degree of financial responsibility he currently bears for his family's welfare.

The question of what method shall be used to give financial aid to medical students is a complex one. This issue must be studied in terms of the degree of responsibility which should be shouldered by the individual for his own education and the degree of responsibility which should be shouldered by the society which benefits from medical practice. The 1957 Report of the President's Committee on Education Beyond High School cites the following statement concerning these issues:

"Some hold that, because the individual gains from education, and because education beyond high school is voluntary, it is the responsibility of the individual to pay for the services he gets. Others hold that society should provide free educational opportunities as long as they are using them advantageously, because society cannot survive and prosper without an educated citizenry. Neither point of view has persuaded the majority of our citizens."

If society aided the medical student from the first point of view, it would do so by *granting loans* which would be repaid to the grantor. Aid to medical students from the second point of view would be derived from *non-refundable grants or scholarships.* A proper balance should be found between these two methods.

The medical student himself constitutes one source of opinion in respect to the balance between these methods of financial aid. Data on the 1959 graduating class of medical students points to the fact that the students favor a 50-50 division between loans and scholarships as a basis of financial aid. Given this proposition, excluding the scholarships that have regularly been available, what are the dimensions of the additional help needed by the medical students?* The table below represents an estimate of the answer to this question based on the experience and the opinion of the 1959 graduating class.

SUMMARY INFORMATION

1.	Total Indebtedness of Members of 1959 Graduating Class Who Have Loan Liabilities and Whose Total Liabilities are Greater Than Their Total Assets	$9,609,070
2.	Estimate of Average Indebtedness of These Students per Medical School Year If Indebtedness Were Evenly Distributed	$2,400,000
3.	Estimated Cost of Financial Aid per Medical School Year If Enough Scholarships are Provided to Decrease Debt of These Students By 50%	$1,200,000
4.	Estimated Total Amount of Additional Scholarships Per Year for All Four Classes in Medical School	$4,800,000

Association of American Medical Colleges

*Approximate total amount of scholarship aid received by the 1959 graduating students: $2.88 million. (If evenly distributed over the four years: $720,000 per year for this class.)

This Section is for you to voice your convictions, comments, and queries on all subjects political, economic, historic, humorous, scientific or otherwise, to many physicians. Writings not sufficiently formal and too brief for an editorial or a scientific manuscript are requested. Clinical and research observations, no matter how brief, similar to those in *The Lancet* (London), are particularly encouraged.

LATEST "MARCH OF MEDICINE" FEATURES "MD USA"

The latest in the Smith Kline & French Laboratories' "March of Medicine" series will be previewed Monday, May 23, 8:00-9:00 p.m. at the Mayo Civic Auditorium in conjunction with the annual meeting of the Minnesota State Medical Association. "MD USA," an unusual color documentary which gives insights into the skill and understanding of free American physicians as they practice in widely scattered sections of the nation, will be seen on KSTP-TV—Channel 5, Twin Cities, May 27, at 7:30 p.m. CDT. Viewers in other areas are advised to consult local NBC-TV listings.

The "March of Medicine" series, which is produced by SK & F in cooperation with the American Medical Association, began in 1952. Its programs have won numerous honors including the first Albert Lasker Award for medical journalism in television. "MD International," a documentary on American doctors in foreign lands, last year received the George Foster Peabody Award for "outstanding contribution to international understanding." In addition, the author of this show, Lou Hazam, was presented with a Christopher Award for his writing. He also has prepared the script for the new program, "MD USA."

In Memoriam

JACOB BIEDERMANN

Final rites for Dr. Jacob Biedermann, Thief River Falls physician for forty-three years, were held Saturday, March 5, 1960, in that city.

Doctor Biedermann died Tuesday, March 1, 1960, in Minneapolis at the age of eighty-four. He was born at Star Prairie, Wisconsin, June 14, 1875, where he attended grade school, and he attended high school in Stillwater. He graduated from the University of Minnesota Medical School in 1904 and interned at a Stillwater hospital from 1904 to 1906.

In 1906, he established a practice in Argyle and was there until 1915 when he moved to Thief River Falls, maintaining an office in the present Elks Building. He retired from practice in 1958 and moved to Austin, where he lived with his son, Dr. George Biedermann, for some time. In 1959, he moved to Minneapolis, where he had made his home since that time.

Doctor Biedermann during his long practice in Thief River Falls was affiliated with Physicians Hospital, later Northwestern Hospital.

He was a member of the Red River Valley Medical Society, the Minnesota State Medical Association and the American Medical Association. He received his Fifty-Club membership in 1954 from the Minnesota State Medical Association.

Surviving are one daughter and three sons: Mrs. Robert Conger (Mary Alice) of Haddonfield, New Jersey; Robert of Minneapolis; Dr. George of Austin; and Dr. John of Lake Forrest, Illinois. He was preceded in death by his wife.

MAURICE D. COOPER

Dr. Maurice D. Cooper, a pioneer Winnebago physician, died March 25, 1960, at Methodist Hospital in St. Louis Park. He was seventy-eight years of age at the time of his death.

Doctor Cooper came to Winnebago in 1908, following graduation from the School of Medicine at the University of Minnesota. On July 4, 1909, he was married to Miss Gertrude Shardi of Minneapolis. Mrs. Cooper died last fall.

Active and interested in civic affairs of his community, Doctor Cooper for many years was active in the Town and Country Club, the Kiwanis Club, the Winnebago Sportsman's Club, and many other organizations. The Community Club tendered Doctor Cooper a dinner in his honor in 1946.

A physician of the "old school", Doctor Cooper was educated at the Parksville, Missouri, Academy and at the University of Minnesota, where he earned his M.D. degree in 1907. In recent years, he had been associated in the practice of medicine and surgery with Dr. J. L. Mills.

Doctor Cooper was a member of the Blue Earth Valley Medical Society, the Minnesota State Medical Association, the American Medical Association, and the Tri-State Medical Association. He had served as advisor to the Cedar Valley Area Council of the Boy Scouts; as a director of the Winnebago Chapter of the Red Cross; Director and Secretary of the Community Club, and President of the Riverside Town and Country Club.

There are three surviving children: a daughter, Mrs. Marshall (Doris Jean) Sawyer of Golden Valley; and two sons, Merlin, Phoenix, Arizona, and Preston, Granada Hills, California.

JAMES R. ELSEY

Dr. James R. Elsey, Glenwood physician and surgeon, died March 20, 1960, at the age of eighty-nine years.

Doctor Elsey was born June 11, 1870, in Northwood, Ohio, and moved to Minnesota as a young boy of twelve with his parents, the Reverend and Mrs. Edward G. Elsey.

He attended Geneva College in Beaver Falls, Pennsylvania, and graduated from George Washington University Medical School in St. Louis, Missouri. He was married to Bertha Ellen McClintock, March 21, 1900.

After practicing medicine for four years in Houston and Monmouth, Ohio, and Chokio, Minnesota, Doctor Elsey moved to Glenwood in 1904 and practiced there until his retirement in 1948.

During World War I, he served as an army surgeon with the occupation army in Germany.

Doctor Elsey was the first commander J-R-D Post of the American Legion in 1920, and also served as Mayor of Glenwood City.

He was a member of the West Central Minnesota Medical Society, the Minnesota State Medical Association and the American Medical Association. In 1947, the Minnesota State Medical Association granted him Life Membership, and in 1951, he was granted membership in the Fifty-Club of the State Association. The community of Glenwood honored Doctor Elsey in 1948, for fifty years of medical practice.

Surviving are one sister, Edna Elsey, Ferndale, Michigan, and three grandchildren, Roberta, William and Gweneth Elsey, all of Glenwood.

EMANUEL S. LIPPMAN

Dr. Emanuel S. Lippman, Minneapolis pediatrician, died February 24, 1960, at the age of fifty-four years.

He was a lifelong Minneapolis resident, a graduate of the University of Minnesota Medical School, an Assistant Clinical Professor of Pediatrics at the University of Minnesota and former Chief of Pediatrics at Mount Sinai Hospital.

His professional memberships included the American Board of Pediatricians, American Academy of Pediatrics, Northwest Pediatrics Society, the Hennepin County Medical Society, the Minnesota State Medical Association and the American Medical Association.

Doctor Lippman was a member of Beth El Synagogue.

94 to 6 BONADOXIN® stops morning sickness

When she asks "Doctor, what will it be?" you can either flip a coin or point out that 51.25% births are male.[1] But when she mentions morning sickness, your course is clear: BONADOXIN.

For, in a series of 766 cases of morning sickness, seven investigators report excellent to good results in 94%.[2] More than 60 million of these tiny tablets have been taken. The formula: 25 mg. Meclizine HCl (for antinauseant action) and 50 mg. Pyridoxine HCl (for metabolic replacement). Just one tablet the night before is usually enough.

BONADOXIN—DROPS and Tablets—are also effective in infant colic, motion sickness, labyrinthitis, Meniere's syndrome and for relieving the nausea and vomiting associated with anesthesia and radiation sickness. See PDR p. 795.

EMANUEL S. LIPPMAN

(Continued from Page A-68)

He served overseas with the rank of Major during World War II.

Survivors include his wife, Helen A.; a son, Harry S.; a daughter, Cathie-Ann; his mother, Mrs. Katie Lippman, all of Minneapolis, and four brothers, Laby, Minneapolis; Dr. Hyman S., St. Paul; Lazarus, Seattle, Washington, and Sidney in New Jersey.

JAMES S. McCABE

Dr. James S. McCabe, of Mendota Heights, died April 4, 1960, at the age of forty-seven years.

Doctor McCabe was graduated from Louisiana State University in 1939 and was Chief of Staff in Obstetrics at St. Luke's Hospital in 1957. He was a veteran of World War II.

Doctor McCabe was a member of the Ramsey County Medical Society, the Minnesota State Medical Association, the American Medical Association, and the Minnesota Obstetrical and Gynecological Society.

Survivors include his wife, Marion C., daughters, Patricia, Diane and Frances, and sons, James S. and Hugh Bernard, all of Mendota Heights, and sisters, Mrs. O. C. Sehnert, Barrington, Illinois, Mrs. Herbert Shipman of Niles, Illinois, and Mrs. Anthony Peters, Chicago, Illinois.

MARY McCOY

Dr. Mary McCoy, Duluth's first woman physician, died September 14, 1959, at the age of ninety-nine years.

She was born November 11, 1859, in Waterloo, Michigan. Her education included two years of general education at Chelsea College and three years at the University of Michigan School of Medicine. After serving for two years as an anatomy instructor at the University, she began the practice of medicine in Duluth in 1890.

Doctor McCoy was active in the woman suffrage movement in Duluth prior to the adoption of the 19th amendment of the U. S. Constitution.

Doctor McCoy retired when she was about seventy-eight. Her husband was Royce McCoy, a Duluth bookkeeper.

Doctor McCoy was honored May 12, 1958, with thirteen men physicians for long service to the medical profession at a dinner in the Northland Country Club, Duluth.

Doctor McCoy was a member of Pilgrim Congregational Church, a life member of Zenith Chapter, Order of Eastern Star and was a member of the St. Louis County Medical Society, the Minnesota State Medical Association and the American Medical Association.

Surviving is a sister, Mrs. Pauline Polrer, Wentworth, Wisconsin; two grandchildren, and four great-grandchildren.

CARLE B. McKAIG

Dr. Carle B. McKaig, who served as a doctor in the Pine Island village and surrounding area for fifty-three years, died March 20, 1960, in St. Mary's Hospital in Rochester after an illness of about four weeks. Doctor

McKaig was seventy-seven years old at the time of his death.

For twenty-seven years, he served as a member of the Pine Island School Board. For twenty-five of those years, he was chairman. Doctor McKaig was Pine Island's Health Officer for a quarter of a century. For many years, he served as Chief of Staff of the Zumbrota Community Hospital. Doctor McKaig was also President of the Olmsted County Medical Society, now the Zumbro Valley Medical Society, and the Southern Minnesota Medical Society.

Doctor McKaig was born in Warsaw, Indiana, the sixth child in a family of ten, on June 24, 1882. The family lived in Lincoln, York, and Omaha, Nebraska, Minneapolis and Sioux City, Iowa, in later years.

He attended Morningside College, graduating with a B.S. degree. In 1906, he graduated from the Sioux City College of Medicine and came to Pine Island in 1907.

Doctor McKaig was a member of the Zumbro Valley Medical Society, the Minnesota State Medical Association, and the American Medical Association. In 1957, he was honored for observance of fifty years of practice by the Minnesota State Medical Association.

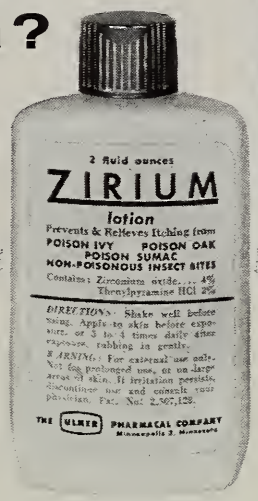
Survivors include a daughter, Mrs. James Spuhler, Ann Arbor, Michigan; a brother, Ray, of Boise, Idaho; and sisters, Mrs. Frank Lake, of Sioux City, Iowa, and Mrs. A. B. Copeman of Grundy Center, Iowa.

HARRY NICHOLAS SUTHERLAND

Dr. Harry N. Sutherland, Ely, passed away February 28, 1960, at the age of seventy-five.

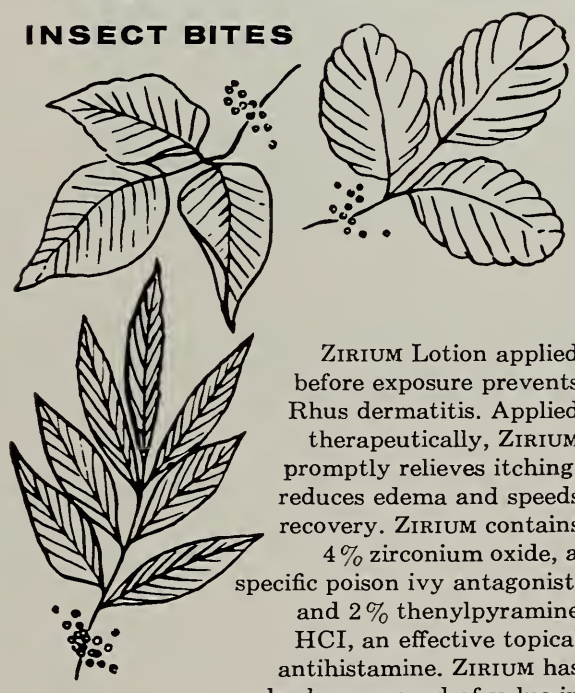
Doctor Sutherland was associated with Doctors Ayres and Parker at the Shipman Hospital from 1913 to 1942. He was a junior partner with Doctor Ayres from 1942-44 and was a senior partner in the firm of Doctors Sutherland and Grahek from 1944-1954. He also served as city health officer for fourteen years.

Doctor Sutherland was born in Madison, Wisconsin, on March 14, 1884, and graduated from Central High School in Madison in 1904. He graduated from the University of Wisconsin in 1909, and completed his studies in 1912 at Rush Medical College. He served his internship at the Children's Memorial Hospital, Chicago, in 1912-1913.



He was a member of the Presbyterian church, an honorary member of Kiwanis International, and had been a member of the Masons (A.F. and A.M. Lodge) for fifty-four years. He was a charter member of the Wisconsin Chapter of the Acacia fraternity, was a member of the Phi Rho Sigma medical fraternity, and was a member of the Range County Medical Society, a life member of the Minnesota State Medical Association, and the American Medical Association.

Surviving are his wife, Doris; one daughter, Mrs. Jack Beuk (Carolann), Hinsdale, Illinois; two sons, Harry Sutherland, Ferguson, Missouri, and George Sutherland, Silver Bay, Minnesota, and eleven grandchildren. Also listed among the survivors are three sisters.



JOHN FELIX TRAXLER

Minneapolis 16, Minnesota 14

April 11, 1960. Doctor Traxler was sixty-nine years of age at the time of his death.

Born at Le Center, Doctor Traxler studied in the high school there, at St. Thomas Academy, St. Paul, and St. John's University, Collegeville. He was graduated from Creighton University School of Medicine, Omaha, in 1915. After spending a year's internship in St. Joseph's Hospital, St. Paul, he began his practice at Henderson in 1916.

He served as a Lieutenant in World War I, and was the first commander of the American Legion post at Henderson.

He had served as a member of the Henderson school board and was a past president of the Nicollet-Le Sueur Medical Society. He also belonged to the Minnesota State Medical Association and the American Medical Association.

Survivors include his wife, Marie; four daughters, Mrs. Harry Holtz, Mrs. George H. Smith and Kitty Jo of St. Paul, and Sister Mary Peter of the School Sisters of Notre Dame, of New England, North Dakota; six brothers and two sisters, Martin, Theodore, Raymond and Mrs. Michael Kehoe of Le Center, and Nicholas, Mankato, Neil and Francis of Minneapolis, and Mrs. Michael Reardon of New York. Six grandchildren also survive.

HARRY B. ZIMMERMANN

Dr. Harry B. Zimmermann, retired chief of the Miller Hospital (St. Paul) medical staff and widely-known St. Paul surgeon, died March 11, 1960, at St. Petersburg, Florida.

Doctor Zimmermann, a native of St. Paul, was Emeritus Clinical Professor of Surgery at the University of Minnesota Medical School and Vice President of the Board of Directors of Miller Hospital.

He began his medical career in 1911, two years after graduation from the Columbia University College of Physicians and Surgeons.

After passing the state medical board examination in St. Paul, Doctor Zimmermann returned to New York where he served at the Manhattan Maternity, Bellevue and New York hospitals.

He was resident surgeon general in New York General Memorial Hospital before returning to St. Paul in 1913.

During World War I, he served overseas with a base hospital and in World War II he was senior consulting surgeon at Veterans Hospital in St. Paul.

He was a member of the Council of the Minnesota Historical Society and was on the Hallie Q. Brown Community House Board of Directors.

He served as consulting surgeon at St. Luke's and Shriners Hospitals and as a member of the staff of Mount Sinai Hospital, Minneapolis.

A member of the Ramsey County Medical Society, Doctor Zimmermann was granted life membership in the Minnesota State Medical Association in 1956. He was also a member of the American Medical Association.

He is survived by his wife, Mary P., and a son, Dr. Bernard Zimmermann, St. Paul; a daughter, Mrs. David Minard of Bethesda, Maryland; a sister, Mrs. Emil E. Nelson of St. Paul, and six grandchildren.

More gastric acid neutralized faster...with new Creamalin®

ANTACID TABLETS

ACID NEUTRALIZATION WITH LEADING ANTACID TABLETS (PER GRAM OF INGREDIENTS)[1]

Tablets were powdered and suspended in distilled water in a constant temperature container (37°C) equipped with mechanical stirrer and pH electrodes. Hydrochloric acid was added as needed to maintain pH at 3.5. The volume of acid required was recorded at frequent intervals for one hour.

GREATLY HEIGHTENED REACTIVITY to acid characterizes the action of New Creamalin Antacid Tablets.[1,2] They act faster and longer than other leading tablets and neutralize considerably more acid.[1] These tablets provide virtually the same effects as a liquid[2] with the convenience of a tablet. New Creamalin tablets give faster, greater and more prolonged relief.

NOT CONSTIPATING, New Creamalin Antacid Tablets will not produce "acid rebound" or alkalosis. They have a pleasant taste.

Creamalin, trademark reg. U. S. Pat. Off.

EACH NEW CREAMALIN ANTACID TABLET contains 320 mg. of specially processed, highly reactive, short polymer dried aluminum hydroxide gel (stabilized with hexitol), with 75 mg. of magnesium hydroxide.

Adult dosage: Gastric hyperacidity—2 to 4 tablets as necessary. Peptic ulcer or gastritis—2 to 4 tablets every two to four hours. Tablets may be chewed, swallowed whole with water or milk, or allowed to dissolve in the mouth.

How Supplied: Bottles of 50, 100, 200 and 1000.

The Physician's Diary

Drs. F. E. Mork and **Harold Mork**, of the Mork Clinic in Anoka, announce the appointment of **Dr. Herman D. Bentz** to their staff. Doctor Bentz is a native of Grand Rapids, Minnesota, and a graduate of the University of Minnesota Medical School. He will serve the Clinic in the capacity of surgeon.

* * *

Virginia, Minnesota, physicians, **Drs. D. J. Richter** and **T. J. Gerend**, recently attended postgraduate sessions. Doctor Richter attended the Chicago Medical Society Postgraduate Clinical Conference and Doctor Gerend attended a Pediatrics Symposium in Kansas.

* * *

Dr. C. W. Truesdale, Glencoe, has received notice that he has been appointed to the Governor's Citizens Committee on Aging. He will serve specifically on the nursing home classification subcommittee.

* * *

The Alpha Chapter of the Alpha Omega Alpha at the University of Nebraska College of Medicine has elected **Dr. John C. Ivins**, Mayo Clinic, to alumni membership. Doctor Ivins is a 1939 graduate of the school.

* * *

Two Minneapolis physicians, **Drs. Albert J. Greenberg** and **Arthur C. Kerkhof**, represented Minnesota at the American Society of Internal Medicine annual meeting in San Francisco, California, April 1-3, 1960.

* * *

Dr. E. C. Burseth, Mora, has been elected President of the Kanabec County Association for Mental Health. The group recently held a board orientation meeting for prospective board members.

* * *

"Results of a Specific Investigation in the Circulatory System" was the subject of a talk by **Dr. Hiram Essex**, retired Mayo Clinic physician, to senior students of advanced ability. A complete survey of the results of the investigation were covered and interesting films taken during it were shown.

* * *

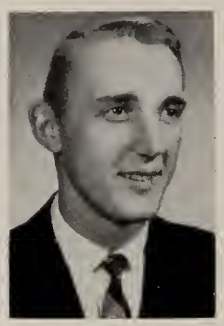
Dr. M. M. Hargraves, Mayo Clinic, spoke to a Downtown Kiwanis Club in Rochester in March. "Environmental Hazards in the Cause of Disease" was the topic of discussion at the meeting. Doctor Hargraves warned that leukemia and other blood diseases are part of the price mankind is paying for progress.

* * *

President of the Northern Association for Medical Education, **Dr. Davitt A. Felder**, St. Paul, has announced the appointment of John W. Hedback as Executive Director of the Association. Mr. Hedback has been Executive Secretary of the American Medical Association's Education Foundation for the past five years.

* * *

A senior consultant in otolaryngology at the Mayo Clinic, **Dr. Henry L. Williams** has been elected President of the American Otological Society. The election took place at the Society's annual meeting in Miami, Florida.



* * *

Dr. Hendrik J. Svien, Mayo Clinic, has been elected an honorary member of the St. Olaf College chapter of Phi Beta Kappa, national honor society for scholarship.

* * *

Fulda, Minnesota, now has the services of **Dr. Fouad Sukkar**, formerly of St. Paul. Doctor Sukkar is a native of British Sudan, North Central Africa, and graduated from the British Medical School of Alexandria, University of Alexandria, Egypt.

RURAL MEDICAL SCHOLARSHIP AWARDED

A University of Minnesota Medical School freshman who likes people and believes that he can serve them best through science, has been awarded the 1959 Rural Medical Scholarship presented annually by the Minnesota State Medical Association.

The eighth recipient of the $4,000 scholarship is George Bruce Gerstenkorn, a native of Belgrade, Minnesota. According to the terms of the scholarship, Mr. Gerstenkorn will receive $1,000 each year for four years with the provision that he promises to practice medicine for at least five years in a Minnesota community in need of a doctor.

The son of Mrs. Clara Gerstenkorn of Belgrade, the twenty-two-year-old 1959 scholarship winner graduated from the public schools of that community in 1955. He received his pre-medical training at St. Olaf College in Northfield, Minnesota.

According to Dr. F. J. Elias, Duluth, chairman of the Rural Medical Scholarship Committee of the Minnesota State Medical Association, the scholarship has a dual purpose; to assist a worthy and outstanding student to meet the cost of medical education and to insure a future supply of physicians in non-metropolitan Minnesota communities.

Three previous winners of the rural medical scholarship are now in medical practice. They are: Richard Engwall, M.D., Ivanhoe; Leland Christenson, M.D., Maple Plain, and Myron Doebler, M.D., Ellendale. Carl E. Christenson, M.D., the fourth recipient, is currently completing his internship and will practice medicine in the western community of Clinton, Minnesota, after July 1, 1960.

Scholarship winners in training at the University of Minnesota Medical School, in addition to Mr. Gerstenkorn, are Edward S. Peterka, Aurora; Vincent R. Hunt, Anoka and LeRoy Mueller, Belle Plaine.

Two Mayo Clinic staff members have been named among sixty-one delegates to represent Minnesota at the White House Conference on Children and Youth. They are **Dr. George B. Logan** and **Dr. John S. Pearson.** Doctor Logan is from the Pediatrics Staff.

* * *

Dr. Bernard Zimmerman, St. Paul, has been appointed head of the West Virginia University Medical Center's Department of Surgery. Doctor Zimmerman is now a Professor in the Department of Surgery, University of Minnesota Medical School. His new appointment will be effective approximately July 1, 1960.

* * *

Dr. Hendrik J. Svien, Mayo Clinic neurosurgeon, addressed 600 foot specialists in Chicago at the three-day Tenth Annual Midwest Podiatry-Chiropody Conference. He spoke on neurosurgical conditions which manifest themselves in the feet.

* * *

Slayton physician, **Dr. Hugh D. Patterson,** recently spoke at a meeting in Lake Wilson, Minnesota. He spoke on ways of getting a doctor and how to treat him if one should come. Lake Wilson citizens have formed a Doctor Call Committee.

* * *

The St. Paul Dispatch of March 30, 1960, had a feature article on the Tumor Board of the St. Paul Chapter of the American Cancer Society. The Board is a group of medical men who banded together in the hope of acquiring more knowledge and exchanging ideas about cancer and helping its victims. It was originated in 1953 by Dr. Davitt A. Felder and is now headed by Dr. John Noble, Ancker Hospital and Dr. Lloyd D. MacLean, Chief of Surgery at Ancker. The Board meets from 8:00 a.m. to 9:00 a.m. the first and third Thursdays of every month to discuss cancer cases that have been submitted to them by medical men of the area.

* * *

Dr. Henry W. Meyerding, Mayo Clinic, was chosen one of the honorary sponsors of the centennial dinner of the New York Medical College. The dinner commemorated the founding of the New York Medical College at the outbreak of the Civil War.

* * *

A staff member of the Worthington Clinic since June 1948, **Dr. R. W. Robinett** has accepted an appointment as Instructor in the Department of Internal Medicine at the University of Michigan. Doctor Robinett will assume his duties in the Medical School at Ann Arbor on June 16. He will be assigned work in the field of allergies.

* * *

The Annual Clinical Reviews, a program of lectures and discussions on problems of current interest in general medicine and surgery was held in Rochester, April 4-6. Clinical Reviews is designed to be particularly useful to the doctor whose practice brings him into contact with the whole range of human illness. More than seventy Mayo Clinic consultants spoke, led discussions and con-

ferences and presented films. Members of the Clinical Reviews committee were **Dr. E. D. Bayrd**, chairman; **Dr. D. T. Carr, Dr. P. E. Bernatz, Dr. A. B. Hayles, Dr. R. C. Roesler** and **Dr. M. G. Brataas.**

* * *

Dr. H. D. Mori, formerly of Rochester, has opened practice in the Clinic Building in Grand Meadow. Doctor Mori is a native of San Pedro, California, and a graduate of the University of Chicago School of Medicine.

* * *

Dr. George E. Nelson, Jr., a former fellow in Orthopedic Surgery in the Mayo Foundation in Rochester, is now located in Minneapolis.

* * *

Doctors Memorial Hospital in Minneapolis has resumed its former name of Eitel Hospital. The hospital was named Eitel from the time it was founded in 1912 until 1954. The name, Doctors Memorial, was selected as a means of paying tribute to the physicians who had helped build its reputation for service to the community. Announcement of the name change was made jointly by **Dr. A. C. Olson**, President of the hospital's Board of Directors and Clarence R. Chaney, Vice President.

* * *

Dr. Jan H. Tillisch, Mayo Clinic, is chairman of the Board of Visitors of the Air University for 1960. The Board of Visitors of the Air University is composed of outstanding educators and business executives of the nation, and it meets at least once a year to evaluate the management, curriculum, methods of teaching and the facilities of the Air University, which is the professional education center of the U. S. Air Force.

* * *

Twenty-four fellows of the Mayo Foundation have completed their fellowships or terminated their periods of assignment. These include: **Drs. F. H. Bledsoe, P. J. Conner, Jr., H. A. Faust, Albert Frischknecht, E. P. Gerber, W. P. Keefe, W. C. Mitchell, G. E. Nelson, Jr., D. H. Overton, Jr., E. Q. Parr, J. A. Ramsdell**, and **D. L. Wilbur.**

* * *

A three-day session of the American College of Surgeons was scheduled for April 11-13, in Minneapolis. A special one-day program was held in Rochester April 14. Participating in the meetings were **Drs. N. Logan Leven, Dr. Norbert J. Lilleberg, Dr. Charles E. Rea** and **Dr. Wallace P. Ritchie**, all from St. Paul. Also participating were **Dr. Horace G. Scott, Dr. Yoshio Sako, Dr. Harold F. Buchstein** and **Dr. Owen H. Wangensteen** from Minneapolis; **Dr. Edward S. Judd** and **Dr. Joseph Pratt**, Rochester, and **Dr. Josiah Fuller of Duluth.**

* * *

Dr. Herman J. Moersch, senior consultant in medicine and a member of the staff of the Mayo Clinic since 1926, retired from the active practice of medicine on April 1, 1960, and shortly thereafter assumed the Post of Director of Education and Research for the American College of Chest Physicians. Doctor Moersch was born in St. Paul and received the degree of Doctor of Medicine in 1921 from the University of Minnesota. Doctor Moersch was President of the American College of Chest Physicians in 1956 and in the same year he was elected President of the staff of the Mayo Clinic. He is currently Vice Chairman of the Section on Diseases of the Chest of the American Medical Association and will advance to the post of Chairman in June, 1960.

* * *

Two films for women viewers were shown by the Ramsey County Cancer Society early in April at the Cancer Information Center. **Dr. Erick Y. Hakanson** and **Dr. Rodney Sturley**, St. Paul, presented a period for questions and discussions.

* * *

The "Town Topper" column in the *Minneapolis Star* recently contained a feature story on **Dr. Harlow Hanson**, health officer for Bloomington. Doctor Hanson has been Health Officer for thirty-four years in Bloomington. He is a native of Hutchinson and graduated from the University of Illinois Medical School.

* * *

Dr. David T. Carr, Mayo Clinic, was the guest speaker at a recent meeting of the Elton Hills PTA meeting. Doctor Carr showed slides and spoke on his four-day trip to Moscow, Russia.

* * *

Dr. Thomas B. Magath, internationally known authority on clinical pathology and parasitology, and a member of the staff of the Mayo Clinic since 1921, retired from active practice on April 1, 1960, and is residing in Sarasota, Florida. Doctor Magath was born in Oxford, Georgia, and received his degree of Doctor of Medicine from the University of Illinois College of Medicine in 1919.

* * *

Dr. and Mrs. L. H. Bendix of Annandale, recently returned from a two weeks' stay at Fort Lauderdale, Florida, where Doctor Bendix attended the two-week Minnesota Medi-Clinic sessions. The meetings were conducted by medical men from the University of Minnesota and from Minneapolis. **Dr. Robert Ransom**, Osseo, was also in attendance.

* * *

Dr. Giles A. Koelsche, consultant in medicine in the Mayo Clinic and Assistant Professor of Medicine in the Mayo Foundation, Graduate School, University of Minnesota, was installed as President of The American College of Allergists at the sixteenth annual meeting of

Members of the hospital staff in Redwood Falls honored **Dr. W. A. Brand,** Redwood Falls, on his eighty-fourth birthday.

* * *

Dr. Robert J. Meyer, health officer for Golden Valley, announced that he is moving to Bethany, Oklahoma, where he will continue in medical practice. Doctor Meyer has been in Golden Valley since 1954. **Dr. Stanley Stone** and **Dr. Wallace Anderson** have taken over Doctor Meyer's practice.

* * *

The Karlstad Hospital staff will have an addition next fall, when **Dr. Duane Pansegrau,** formerly of Sioux City, Iowa, joins the group.

Here's the BIG news in professional liability insurance –

NO ADDITIONAL PREMIUM FOR PARTNERSHIP COVERAGE

and NO EXTRA PREMIUM FOR COVERAGE OF EMPLOYED PHYSICIANS OR TECHNICIANS

All other malpractice policies have an additional charge of 20 per cent or more of the individual rate to provide partnership coverage. Additional charges are also made in other policies by reason of the employment of other physicians, surgeons, x-ray or laboratory technicians. **Physicians & Surgeons Underwriters Corporation makes no additional charge for such coverage.** "Physicians & Surgeons" is administered by a medical Board of Directors. It is the FIRST COMPANY in Minnesota to offer this partnership and group practice feature, plus a rock bottom basic premium structure and a new broad comprehensive policy.

There are many other features in the Physicians & Surgeons policy that are built in for the protection of the doctor. Write or call today for complete details on this all-risk comprehensive policy.

Replies to advertisements with key numbers should be mailed in care of MINNESOTA MEDICINE, *2642 University Avenue, Saint Paul 14, Minnesota.*

GENERALIST WANTED—Two general practitioners in Northern Minnesota desire association. Good office, hospital and school facilities. Salary open. Partnership later. Write E-674, care MINNESOTA MEDICINE.

RESIDENCY AVAILABLE—Three-year approved residency in Physical Medicine and Rehabilitation in 1300-bed Veterans Administration Hospital with Baylor University College of Medicine affiliation. Regular residency $3,250-$4,165; career residency $6,505-$9,890 (stipend dependent upon qualifications.) U.S. citizenship required. Physicians qualified in specialty of PM&R are in great demand within the VA, private institutions of rehabilitation, private hospitals and private practice. Write Manager, VA Hospital, Houston, Texas.

EXCELLENT OPPORTUNITY for certified or board-eligible pediatrician with established group in attractive Minnesota community. Medical Block Clinic, 412 Main, Red Wing, Minnesota.

WANTED—Young general practitioner for association with small suburban Saint Paul group. Salary and early partnership. Address E-698, care MINNESOTA MEDICINE.

WANTED—General practitioner to take over busy practice in college community in Minnesota. New hospital. Leaving to specialize. Reasonable terms. Address E-719, care MINNESOTA MEDICINE.

OPPORTUNITY to become a partner in an active general practice. Good starting salary. Address E-721, care MINNESOTA MEDICINE.

GENERAL PRACTITIONER—To join busy general practitioner. Northern Minnesota. Excellent hospital —new. Good hunting and fishing. Partnership after about 18 months. Terms will be regulated by training and experience. Would like man by July 1, 1960. Minnesota license required. Contact L. N. Dale, M.D., Red Lake Falls, Minnesota.

BOARD-QUALIFIED ORTHOPEDIC SURGEON—Excellent opportunity, 19-man general practice and specialty clinic in northern Minnesota. Community 15,000. Trade area 60,000. Excellent hospital facilities including rehabilitation center. Heavy industrial. Salary open. Partnership within a year. Contact Dr. W. Woodruff, East Range Clinic, Virginia, Minnesota.

WANTED—Associate in General Practice to eventually take over full practice now grossing over $60,000.00 per year. Beginning salary $12,000.00 to $15,000.00, depending on qualifications. References required. Address E-714, care MINNESOTA MEDICINE.

WANTED—GENERAL PRACTITIONER with pediatric interests to join two young G.P.'s in own new building, Saint Paul. Excellent hospitals and medical school near. Salary to start, early partnership. Address E-720, care MINNESOTA MEDICINE.

EXCELLENT OPPORTUNITY for one or more physicians to practice in completely new economically stable taconite village, with population of over 3,000. Office space immediately available in new Shopping Center. New 50-bed modern hospital with complete facilities to be completed in August this year. New housing available at attractive terms. Hoyt Lakes Civic & Commerce Association, Hoyt Lakes, Minnesota. BA 5-2344.

WANTED—General practitioner. Opening available immediately with a twelve-man established group. Salary and early partnership. Address E-722, care MINNESOTA MEDICINE.

GENERAL PRACTITIONER needed after June 1. Community serving 2,500 or more people—west central Wisconsin. Excellent fishing and hunting areas near. Well-equipped office with present doctor—possible partnership later. Address E-724, care MINNESOTA MEDICINE.

FOR RENT—Nice physician's office, second floor apartment building, 476 South Cleveland, Saint Paul. Highland Park area. Next to dentist. Telephone CA 2-6042; MI 9-0237.

FOR SALE—Bungalow. Ideal office or office-residence arrangement for Physician, Dentist or Attorney. On Main Street, next to city post-office in southeastern Minnesota city of about 3,000 population. Excellent hospital in city. On Mississippi river, affording unusual recreational facilities. Address E-723, care MINNESOTA MEDICINE.

FOR SALE—One Picker portable X-Ray, in perfect condition. Also casettes and film holders. Available July 1, 1960. Write: Dr. E. Ostergaard, Evansville, Minnesota.

FOR SALE BY OWNER—Exclusive city and lake home suitable for professional man, located on west shore of Lake Owasso, 3160 W. Owasso Boulevard. Split level, three bedrooms, with finest of extras. Must see to appreciate. Possession June 1. Call Leo Hoye, Saint Paul, PRospect 1-5135.

when air-borne tree pollens attack...

BENADRYL®

antihistaminic-antispasmodic

gives prompt, comprehensive relief

In sensitivity to tree pollens, BENADRYL provides simultaneous, dual control of allergic symptoms. Nasal congestion, lacrimation, sneezing, and related histamine reactions are effectively relieved by the *antihistaminic action* of BENADRYL. At the same time, its *antispasmodic effect* aids in alleviating bronchial and gastrointestinal spasms. This duality of action makes BENADRYL valuable throughout a wide range of allergic disorders.

BENADRYL Hydrochloride (diphenhydramine hydrochloride, Parke-Davis) is available in a variety of forms including: Kapseals,® 50 mg.; Kapseals, 50 mg. with ephedrine sulfate, 25 mg.; Capsules, 25 mg.; Elixir, 10 mg. per 4 cc.; and, for delayed action, Emplets,® 50 mg. For parenteral therapy, BENADRYL Hydrochloride Steri-Vials,® 10 mg. per cc.; and Ampoules, 50 mg. per cc.

GENERAL INFORMATION

Authors

Manuscripts should be addressed to Arthur H. Wells, M.D., Editor, 915 East First Street, Duluth 5, Minnesota. Telephone RA 7-6636 or JA 5-2319. Original papers prepared for publication solely in Minnesota Medicine will be considered by the Board of Editors providing they fulfill the following editorial standards. Manuscripts should be typed double spaced on white paper with at least 1-inch margins. The original (not a carbon copy) is requested. The title on the first page should be under six words if possible or divided into two parts. The author should give his highest degree, his institutional position or his relationship to a hospital or medical organization which he may be addressing. Pages should be numbered consecutively and the author's last name should appear at the top of each page.

Bibliographical references should appear on a separate sheet entitled References. They should appear and be numbered consecutively in the order in which they first occur in the text (not alphabetically). Citations in the text require reference numbers if the author's or authors' names are not used or if there is more than one reference to the same author or group of authors. All references to author should appear in the list of References and no references should be included which are not in the text. The style and exact punctuation used in the J.A.M.A. references are requested. Journal references should include: *Author's last name, initial., initial.: title of paper. Abbreviated name of journal, volume number: page, year.* Book references should give author, title, edition number, city, publisher and year.

Illustrations (photographs, tables and graphs) should be submitted separately and not combined in the text. There should be a separate sheet entitled "Illustrations" which contains the various types of illustrations listed separately and numbered in the order in which they appear in the text. All photographs must be in black and white, clear cut, contrasting, and on glossy stock. Instructions for combining photographs are acceptable. Any number of illustrations over 4 are charged to the author. Combinations of photographs up to one-half page (6 x 4⅜ inches) count as 1 illustration.

Pneumothorax—Traumatic and Spontaneous

Pneumothorax as a clinical entity has changed considerably over the past fifteen years. Tuberculosis is no longer the essential cause. The author reviews the newer knowledge of pneumothorax as to type, etiologic and physiologic mechanisms, diagnosis and treatment. As always, Kinsella's writings are clear, precise and practical.

THOMAS J. KINSELLA, M.D.
Minneapolis, Minnesota

PNEUMOTHORAX may be induced, traumatic or spontaneous in origin. To the average physician not in frequent contact with it, it is a somewhat mysterious and at times a very frightening condition. The following discussion is presented in an attempt to clarify some points concerning its types and treatment.

Induced Pneumothorax

Induced pneumothorax may be either therapeutic or diagnostic. Therapeutically, it was used very extensively in the past for the treatment of pulmonary tuberculosis, but has been almost completely abandoned since the introduction of the specific anti-tuberculosis drugs. Only a very few pneumothorax patients still remain from the thousands previously treated. Artificial pneumothorax in the presence of free pleural space provides a very effective means of control of recurrent pulmonary hemorrhage from tuberculosis or bronchiectasis.

Diagnostic Pneumothorax

Diagnostic pneumothorax may at times be of help to (1) localize tumor, (2) localize intrapulmonary bleeding, (3) visualize the diaphragm, (4) to replace pleural effusion, and (5) as a preliminary to thoracoscopy. The field for such, diagnostic pneumothorax, however, has been greatly reduced, by special radiographic techniques and the use of planigrams and bronchograms, by the development of right angle lens systems for bronchoscopy and by diagnostic cell study techniques

on sputum and aspirated bronchial secretions. Its use following aspiration of pleural fluid and followed by special x-ray films or thoracoscopy may in certain instances save an individual a major exploratory thoracotomy.

Traumatic Pneumothorax

Traumatic pneumothorax includes those which occur following gross trauma as well as the accidental variety which will be discussed separately. It may follow (1) crushing injuries of the chest, (2) a blow on the chest, (3) closed penetrating injuries as from a bullet or stab wound, (4) open penetrating wounds of the chest wall, (5) birth injury, (6) blast injury, (7) perforating foreign body of the esophagus, or (8) accidental pneumothorax.

The amount of trauma necessary for the production of pneumothorax may vary widely from an almost insignificant amount, a blow, a squeeze, a fall or a single fractured rib to a most severe crushing with multiple fractures or even disruption of the chest wall. A stab wound or bullet wound through the chest may be followed by pneumothorax, but not infrequently bleeding from the lung parenchyma occurs so rapidly that it seals the air vesicles preventing the escape of air and no pneumothorax follows. The passage of a baby through the birth canal is a traumatic crushing type of episode and this plus strenuous efforts at resuscitation may produce a pneumothorax. Blast injury from an explosion, from the rupture of a pneumatic tire, the opening of an air hose in close proximity to the patient's nose and mouth, or an over zealous attempt to expand the lung or to apply artificial respiration through an intratracheal tube may result in pneumothorax. Any sharp object impacted in the esophagus may perforate and if the adjacent lung is punctured, a pneumothorax may follow.

Accidental Pneumothorax

An accidental pneumothorax is one which is produced by some manipulation carried out by the physician. Most frequently, it results from puncture of the lung by a needle or by some manipulation or instrumentation which results in tearing of the pleura. A very common source of accidental pneumothorax previously seen was an attempt to induce an artificial pneumothorax or to refill a pleural pocket in which the lung was close to the chest wall. If the lung was punctured by the needle, air escaped through the wound into the free pleural space collapsing the lung to a greater or less degree. Aspiration of a clear or purulent pleural effusion could also result in collapse of the lung for the same reason, especially if an attempt was made to evacuate the pocket completely. It might also result from suction of air through an aspirating needle left unguarded as the aspirating syringe was emptied of fluid. Many a pneumothorax of this type was not recognized.

All of the classical sites shown in the text books for aspiration of the pericardial sac lie in an area where the pleural cavity or the lung or both must be traversed except the subcostal paraxyphoid puncture site. This is the most favorable site and it is the one which should be used instead of the anterior approach.

Attempts at needle biopsy of an intrathoracic tumor or the pleura may puncture the lung in a non-consolidated area and induce air leakage. A very effective way of establishing an accidental pneumothorax is to aspirate an air filled pulmonary cyst or emphysematous bleb. The straining incident to bronchoscopy or esophagoscopy may also result in an accidental collapse. The surgical operation of dorsal sympathectomy, rib resection, or radical breast operation in a patient with free pleural space may result in tearing of the pleura and collapse of the lung. A very high laparotomy or kidney incision may occasionally result in laceration of the diaphragm and pleura and produce a pneumothorax.

Spontaneous Pneumothorax

Spontaneous pneumothorax can be defined as a pneumothorax which appears out of a clear sky with no antecedent trauma, or manipulation. The margin between spontaneous pneumothorax and traumatic pneumothorax in industrial work may be so small as to be almost nebulous. The mechanism may even be the same, but if it occurs on the job or there is even the faintest hint of a traumatic factor, it is usually called a traumatic pneumothorax. Once thought to be indicative of pulmonary tuberculosis, it is now known to have no direct connection with this disease, although it may occur occasionally in tuberculous individuals through the same mechanism as in anyone else. If the cavity of tuberculosis or of a pulmonary abscess ruptures into the pleural space, a spontaneous pneumothorax follows, but almost immediately an extensive

and very virulent empyema develops leaving no doubt as to its origin. "Spontaneous" perforation of the esophagus usually occurs in the lower third of that structure with rupture into the mediastinum and then secondarily into the pleural cavity on one or both sides with mediastinal emphysema, tension pneumothorax, and empyema.

The most frequent cause of spontaneous pneumothorax is the rupture of a peripheral emphysematous bleb into free pleural space. The bleb may be large or small, most commonly on the small side with some even very minute in size. Such blebs are found in at least a third of normal individuals at the time of intrathoracic surgery and at postmortem examinations. Spontaneous pneumothorax occurs more frequently in younger people otherwise apparently healthy and less commonly among the older age group who have clinical emphysema, either of the interstitial or the bullous type, although it does occur in some of these patients.

These blebs are very thin walled, as delicate as thin tissue paper and rupture very easily. A localized peripheral bronchial obstruction with a check valve mechanism can cause local over-distention of tissue and bleb formation with rupture without any external strain or injury even during sleep. Air then leaks out into the pleural cavity the lung collapsing to a degree depending upon the freedom of the pleural space, the size of the leak and the amount of the check valve action in the local bronchus or in the wall of the bleb and perhaps upon the activity of the patient. The duration of the pneumothorax depends upon the continuation of the leak and the rate of air absorption from the pleural cavity and the treatment which is applied. Some pneumothoraces give a few or no symptoms, some are recognized only accidentally. Some are mistaken for pleurisy, while others give pain, tightness in the chest, and shortness of breath and a few go on to tension pneumothorax which, if reaching a considerable degree, may be a very serious or even fatal complication.

A tension pneumothorax is any pneumothorax in which pressure builds up to a degree which embarrasses the patient. This is not any particular point on the manometer but is related to the patient's vital capacity, respiratory reserve, the compressibility of the lung and flexibility of the mediastinum, as well as to the pressure in the pleural cavity. The deleterious effects of the tension result from the amount of collapse, from reduction of respiratory capacity, through displacement of the heart and mediastinal structures, from compression of the thin walled veins within the thorax interfering with return blood flow, from pain, or tightness, and from intrapleural bleeding if the lung or an adhesion is torn as the lung collapses.

Diagnosis

The first essential in making a diagnosis of pneumothorax of any type lies in thinking of the possibility of such a condition in any patient who has sustained trauma to the chest and in any patient complaining of chest pain or shortness of breath. It is then easy to diagnose. First there is splinting of the chest wall on the affected side, the percussion note over this side is resonant to hyper-resonant, the breath sounds are distant to absent although occasionally if some tension is present there may be an amphoric over-note to be heard. The heart and mediastinal structures may be shifted to the contralateral side with muffled to distant heart tones and a loss of the normal substernal dullness at the base of the heart and deviation of the trachea in the supersternal notch.

The smaller degree of pneumothorax are less readily recognized and x-ray films of the chest may be necessary in order to confirm the suspicion of the condition. A number of patients in whom the diagnosis of spontaneous pneumothorax has been made will give a history of one or more previous episodes of similar nature, diagnosed as pleurisy without x-ray studies and perhaps treated by chest strapping. It is quite probable that at least some of these previous attacks also were spontaneous pneumothorax. Some patients have no pain or other sensation except for a little tightness in the chest especially noticeable when bending over to lace the shoes. Chest roentgenograms early may show only a small apical rim of air easily missed on poor films or unless a careful study is made. Occasionally the condition is simultaneously bilateral. The amount of pneumothorax may at first be small but over a period of hours build up to a considerable volume.

Pneumothorax in traumatic situations may be less easily recognized. Chest pain, immobilization of the side and distant breath sounds, the result of the trauma may confuse the picture. The pneumothorax may be small or even absent at first but becomes evident subsequently because of increase in size following coughing, straining, or lung laceration from fractured ribs. When air and fluid are

present, the fluid level is easily recognizable if the patient is properly postured. The pneumothorax need not be on the side of the greatest trauma, hence may be overlooked. If bilateral or extensive, it may well prove fatal unless properly recognized and adequately treated.

A large rapidly recurrent pneumothorax following severe chest trauma, especially of the crushing type, should always raise the question of a ruptured bronchus as the cause of the picture. Prompt recognition of this situation with early thoracotomy and suture of the bronchial rent may save the function of the involved lung as well as relieve the source of pneumothorax.

Spontaneous pneumothorax runs a variable and quite unpredictable course. It apparently occurs more commonly in the younger individuals without clinical evidence of emphysema although it is occasionally seen in older individuals with marked emphysematous changes or large bullae. In the elderly, it may be much more serious because of associated cardiovascular disease or low respiratory reserve and may easily lead to fatal outcome unless promptly recognized and relieved. The individual attack may be mild or severe, the amount of collapse slight or extensive, and the duration of the leak, short or with continued leakage it may last for a considerable period of time. There may be some relationship to the "cold seasons" for we have repeatedly noted spring and fall "epidemics," with a number of patients with this condition appearing in a short period of time and then several months elapsing before another group appears. There is, however, no history of antecedent, respiratory infection in most of these patients.

There is a definite tendency for recurrence in spontaneous pneumothorax for about thirty percent of the patients who have sustained one attack may be expected to subsequently have another episode on the same or the opposite side. Attempts to precipitate a recurrence of collapse by very strenuous physical activity have in a few instances proved unavailing only to have a recurrent episode occur while sitting quietly in a chair some months afterwards. The uncertainties of the situation and the recurrent time loss with succeeding attacks can create a very distressing situation for these patients.

Treatment

The treatment of pneumothorax may be outlined as (1) conservative, (2) aspiration, single or multiple, (3) continuous decompression by means of an under the water break-over or continuous suction, and (4) surgery, resection of bleb, decortication and obliteration of the pleural cavity.

If the pneumothorax pocket is small, not increasing, and not distressing the patient particularly, the patient may be treated conservatively, allowing the air to absorb from the pleural cavity. This will occur at the rate of 50 to 75 cubic centimeters per day depending upon the normality of pleura and the patient's activities. The patient's activities are usually restricted at least for a few days at the onset. If the amount of the collapse is rather large, the duration of disability may be reduced somewhat by aspiration of air from the pleural cavity, instead of waiting for spontaneous absorption. It is usually advisable to wait for twenty-four to forty-eight hours before aspirating air as an elective procedure if the patient is having no real distress, thus giving the pleura time to seal the leak. Early aspiration or the creation of too high a negative pressure in the pleural cavity may perpetuate the leak. Likewise complete aspiration of all air from the pleural cavity may bring the expanding lung into contact with the tip of the aspirating needle, producing an accidental pneumothorax on top of the original spontaneous collapse.

The best site for air aspiration with the patient propped up slightly in dorsal recumbent position is the second anterior interspace in the mid clavicular line, if the lung is free of the chest wall in this area. If the pneumothorax is large, aspiration in several stages may be advisable for removal of most of the air at one sitting may give severe distress if the lung has been collapsed and atelectatic for a time and does not expand readily.

Tension pneumothorax demands prompt decompression if disastrous results are to be avoided. This is especially true in the patient with cardiovascular disease or a low vital capacity in whom delay in affording relief may well prove fatal. No elaborate apparatus is necessary for decompression of a tension pneumothorax. All one needs to do is to insert an number 18 gauge needle into the pleural cavity in the second interspace anteriorly. The pressure in some of these pockets may be sufficient to blow the plunger of the attached syringe across the room, decompressing the pocket considerably through the open needle. Additional air can be expressed through the needle by requesting the patient to strain or it may be aspirated with a

syringe. It must not be forgotten in dealing with tension pneumothorax that the condition tends to recur. Therefore the physician must either make provision for repeated needle aspiration, or better yet for continuous decompression of the pocket by catheter.

Another thing which must be remembered in these days of rapid transportation by land and by air is that Boyle's law has not been repealed and any closed pocket of gas under increasing altitude or diminishing barometric pressure as in a transcontinental trip or an airplane flight may become a tension pocket and demand prompt decompression. Continuous decompression is best accomplished by insertion of a blunt needle or cannula, a flat S shaped Clagett cannula, or better, a small rubber or plastic catheter into the pleural cavity, connecting it to some mechanism for intermittent or continuous removal of air.

The second interspace anteriorly in the midclavicular line is the site of choice if the lung is free at that point. A straight needle with a very blunt point is adequate for simple aspiration but is not suitable for continued decompression for it is difficult to maintain in proper position and the point although blunt can easily tear the surface of the expanding lung, creating an accidental pneumothorax. A straight blunt cannula eliminates the lung tearing danger but presents the other disadvantages of a straight needle. The flat S shaped Clagett cannula with its blunt tip and side ports near the tip is distinct improvement over the needle or straight cannula as its inner end lies parallel to the chest wall while its outer attachments lie parallel to the skin. The chief argument against it is that it gives considerable discomfort from pressure in the chest wall and the parietal pleura inside.

The best solution to this problem is the insertion of a small rubber or plastic catheter number 12 or 14 gauge. If it is rather soft and is inserted through a cannula directed slightly upwards through the second interspace for a couple of inches it will come to lie parallel to the surface of the expanding lung and be lifted up by it as it expands and will adequately empty the air pocket and not interfere with expansion of the lung. The catheter may then be connected by tube to an under the water break-over, placed well below the patient's body level with the end of the tube not over one centimeter under the surface of water. This will allow adequate escape of air decompressing any pocket to a pressure of one centimeter of water above atmospheric pressure. If the patient will then strain or cough, additional air will be forced out, the water seal preventing suction of air back into the chest through the tube.

A controlled negative pressure suction machine may also be attached to the catheter but care must be exercised to avoid too high a negative pressure or the leak may be reopened or perpetuated. The desirable setting is to have rather large output volume at a very low negative pressure of not over four or five centimeters of water. With such treatment, in the majority of patients the leak will cease and the lung expand to the chest wall rather rapidly. When the lung is well expanded and seems to stay out, the tube may be clamped off for twenty-four to forty-eight hours and then if there is no recurrence, may be removed from the pleural space. If there is fluid or blood to be removed from the pleural cavity this will not be accomplished through an anterior catheter. This must either be aspirated through a posterior site or a posterior basal catheter inserted to take care of it.

Most patients with spontaneous, traumatic or accidental pneumothorax will seal the leaks and expand the lung under such a program. There are, however, a few in the spontaneous group and a few in the traumatic group in whom larger leaks do not seal promptly, and continuous air leakage occurs. This is particularly true with rupture of a larger bleb or cyst in the lung or with rupture of a bronchus or in traumatic or spontaneous perforation of the esophagus. These patients demand prompt surgical intervention, suture of the leak or repair of the bronchus or esophagus if the patient is to be saved.

Recurrent Spontaneous Pneumothorax

Recurrence of spontaneous pneumothorax on the same or opposite side occurs in at least thirty percent of individuals, some on many occasions. If the patient is young and intelligent, he will recognize the recurrence promptly and place himself under a physician's care immediately. If he is a city dweller close to a hospital and medical care, the danger to life is probably quite small, for relief can probably be afforded quite promptly. If on the other hand he lives in a remote area or is a traveling salesman or has some other occupation which takes him into strange communities, or if he takes hunting or fishing trips to remote locations, an extensive recurrence away from home

could prove serious if not fatal. The same applies to an airplane pilot, to the passenger who travels much by air, to one who works in a hazardous occupation, or one in which he is responsible for the safety of many others, or where his sudden collapse may endanger himself or others. The time and economic loss and the repeated hospital expense from recurrent attacks must also be taken into consideration in determining whether surgical intervention should be recommended. It is not always the number of attacks which the patients have had but the individual circumstances involved in each particular case which should determine the treatment to be recommended.

Rarely do we operate for a first attack. However, in the case of the airplane pilot, or the man who lives or travels in out-of-the-way places and others in related categories, we would be inclined to recommend surgical intervention without delay. The same should be said also for the patient who has a progressive hemothorax with his pneumothorax. It must be remembered that neither spontaneous absorption nor expansion by aspiration or catheter drainage does anything to obliterate the pleural cavity or prevent recurrence.

Surgical attack in this condition has four primary functions: to control air leakage, to stop bleeding, to expand the lung, decorticating if necessary, and to obliterate the pleural cavity. The leaking area if still active may be easily identified during thoracotomy by expansion of the lung under water. The leak may be from a bleb of some size but frequently will be from a small marginal emphysematous bleb. Ligation or suture or excision of the leaking bleb will control the leak. The lung under bag pressure will then expand unless bound down by a fibrin membrane from fluid or blood which may be removed by decortication. Bleeding usually from the parietal side from a torn adhesion is easily controlled.

Obliteration of the pleural cavity may be accomplished in various ways. Twenty-five years ago poudrage with talc through cannulae under telescopic guidance was painful and produced at best an uneven and spotty obliteration of the pleural cavity. The obliteration which may follow blood or fluid following collapse may likewise be spotty or even entirely absent.

The injection of irritating substances such as hot water, hypertonic saline or glucose solutions, talcum powder, zephiran chloride, or others will irritate the pleura and obliterate the space upon expansion, but unless used in large amounts to cover all surfaces will not seal all areas of the pleural cavity. Theoretically, an irritating non-toxic gas should produce a complete pleural irritation and obliteration. Pleurectomy will certainly produce adhesions between the lung to the chest wall, but unless a complete parietal excision is done, there may still be unobliterated areas and recurrence of pneumothorax may still occur. (I have recently seen such a recurrence.) Practically, pleurectomy is not necessary in order to stick the lung to the chest wall. It adds unnecessary trauma to the surgery and increases blood loss, and more serious, it detroys the extra pleural layer which is the thoracic surgeon's friend. Should the patient subsequently require chest surgery on this same side, it will seriously increase the risk and difficulty of the procedure.

Our own preference at open thoracotomy includes excision of leaking area, complete abrasion of pleura both visceral and parietal with dry gauze and then complete inundation of the entire pleural cavity with 1-1000 aqueous zephiran chloride for two minutes followed by irrigation with saline and closure over two drainage catheters for suction.

Blood loss from this procedure has been small (under 250 cc.). Transfusion has been necessary in only seven of the last forty patients so treated. Four had low hemoglobin and were in poor general condition preoperatively and were given a single unit of blood. Three also required decortication and received replacement for blood lost in amounts of 500, 1000, and 2000 cc. There have been no recurrences of pneumothorax on the operated side in any patient treated by this method. One patient developed a spontaneous collapse on the contralateral side some six months following surgery and was operated upon and pleural obliteration carried out on the second side. Five other patients had a history of previous pneumothorax on both sides at different times in the past. Two of these had simultaneous bilateral collapse at the time of surgery, but only one pleural cavity was obliterated. Recovery was uneventful and there has been no recurrence on the opposite side. One patient who had had three attacks on the right and one on the left was operated upon for the recurrent right trouble during pregnancy. Recovery was uneventful.

Abdomino-Presacral Resection for Selected Rectal Lesions

R. W. UTENDORFER, M.D.
Minneapolis, Minnesota

Inaugural thesis presented to Minneapolis Academy of Medicine, December 15, 1958.

THE FINAL status of sphincter saving operations for carcinoma of the rectum awaits further evaluation. Recent contributions[1,2] have enlarged upon previous knowledge[3,4] of the routes of lymphatic spread in rectal carcinoma. In lesions of the upper rectum, published results by surgeons experienced in sphincter preserving techniques compare favorably with those achieved by the Miles procedure.[5] This tends to confirm the belief that lateral spread of malignancies in this area may be of secondary importance because it is likely that wider excision at this level may be achieved by abdominoperineal resection. Thus it may be true that malignant lesions in the mid portion of the rectum can be eradicated with approximately the same chance of cure by either the Miles procedure or by one of the sphincter saving operations.

In spite of these reported favorable results of "pull through" types of operations, there remains reason for disagreement concerning the relative merit of these procedures. The desirability of a functioning sphincter is unquestioned, but the degree of control in some patients following the "pull through" operation is not satisfactory.[6] When satisfactory sphincter function is not retained, the patient is, in effect, left with a colestomy in an inconvenient location.

Failure of sphincter function has discouraged many from using the "pull through" procedure and the conventional abdominoperineal resection remains as probably the most commonly[7] accepted method of treating malignancies in this area.

It is not the purpose of this paper to attempt to compare the various procedures available for use in this location. Our preference is a one-stage abdominoperineal resection for carcinoma of the rectum, reserving anterior resection for those near or above the peritoneal reflection. Anterior resection for presacral lesions is possible, but it is technically difficult, it is attended by frequent complication, and it is not the procedure of choice. Occasionally one will be called upon to treat a lesion in which the Miles procedure would not be desirable, as in a bulky polyp of questionable malignancy.[8] Also there are instances in which preservation of sphincter control is mandatory, for example in an individual who has markedly restricted vision or who is completely blind, making adequate care of a colostomy almost impossible. Mentally deteriorated patients may also be in the category where sphincter preservation is a "must." Confronted with such a situation in a number of patients, a modification of the procedure described by Gordon Murray[9] has been used with satisfactory results. This operation, as originally described, consisted of trans-sacral excision of the rectum, with primary anastomosis, without diverting colostomy. To achieve wider dissection, this has been modified to include an abdominal stage, in addition to the trans-sacral excision.

Technique

Abdominal Stage.—Exploration is carried out through a left lower paramedian incision. The sigmoid, iliac and descending colon are mobilized. When performed for malignancy, an adequate amount of colon consistent with good cancer surgery is resected. The pelvic peritoneum is incised and the rectum dissected as in the Miles procedure. The amount of sigmoid to be included in the resection is placed below the pelvic peritoneum and the pelvic floor is reconstructed. The abdominal wound is then closed.

Perineal Stage.—The patient is placed in the inverted (jack-knife) position and a vertical incision is made from the dorsum of the sacrum to just above the anal margin. The coccyx, the fifth, and half of the fourth sacral bodies are removed after separating their muscular attachments. Entrance into the presacral space is thus achieved, and the bowel previously placed here is delivered through the sacral wound. Resection is performed and reconstruction done by anastomosing the proximal and distal segments. This anastomosis is done with an inner layer of chronic intestinal suture and an outer layer of interrupted silk sutures. Following

completion, a rubber rectal tube is passed through the anastomosis and sutured to the anal skin. The presacral space is drained and the wound closed.

Case Reports

The following cases are reported to illustrate lesions in which this procedure may be used to advantage.

Case 1.—R. T., a man aged thirty-two, was admitted to Minneapolis Veterans Hospital September, 1952. In 1950, he had an exploratory laparotomy at which time a perforation of the sigmoid colon was closed. This was followed by development of a stricture of the sigmoid and an external colonic fistula. In March, 1951, the fistula was excised along with resection of the sigmoid and removal of an ileal fistula. This was followed by a transverse colostomy necessitated by recurrence of colonic fistula. Resection of the sigmoid and recurrent fecal fistula and drainage of a pelvic abscess was performed again in September, 1951. In March, 1952, the sigmoid was again resected with anastomosis 15 cms. from the anal margin. This was followed by development of a pelvic hematoma and recurrence of the sigmoidocutaneous fistula. Examination on admission revealed a functioning transverse colostomy, a number of abdominal surgical scars and a fecal fistula in the lower abdomen. A rectal stricture at 8 cms. was demonstrated, and x-ray revealed residual barium present in the pelvis from previous studies. On September 9, 1952, a modified Gordon Murray procedure was performed. Approximately 15 cms. of colon, including the fistula, was resected and the anastomosis made just above the pectinate line. Postoperatively there was drainage from the presacral space but no fecal fistula was demonstrated. On October 10, 1952, the colostomy was closed. Following this, the patient had good sphincter control, but there was persistent drainage from the perineal incision. In March, 1953, a small fistula in ano extending from the lowermost part of the sacral incision to the pectinate line was excised. This healed rapidly and six months later the patient had a healed wound with normal sphincter control. Recent examination reveals his condition to have remained satisfactory.

Comment.—This patient presented a difficult problem because of six previous surgical procedures, residual colonic fistula and presacral abscesses. His age (thirty-two) and the absence of evidence of malignancy warranted efforts to preserve rectal function, and he was eventually restored to normal rectal continence. One can only conjecture as to the original pathology, but sigmoid diverticulitis probably is most likely.

Case 2.—G. S., a man aged fifty-seven, a duodenal ulcer patient, was found to have a rectal polyp at 10 cm., located on the anterior rectal wall. This sessile polyp with a base of 4 cm. was removed, and on section it was considered to be malignant. No other polyps were demonstrated. On December 31, 1952, a modified Gordon Murray procedure was performed, at which time 16 cms. of bowel was resected. Examination of the resected specimen failed to demonstrate residual tumor. Postoperatively, the sacral wound drained for four weeks, but no fecal fistula developed. This patient has been followed in the clinic and was last seen May, 1958, at which time he was doing well.

Comment.—Resection was elected in this patient because of the probable malignant characteristics of the polyp, although it appeared to have been removed completely. Possible extension through the rectal wall seemed to justify the procedure. As frequently happens, examination of the resected specimen failed to demonstrate residual malignancy.

Case 3.—S. B., a man aged eighty-three, was admitted May 5, 1954, with proven adenocarcinoma of the rectum at 8 cms. The patient had been under treatment for carcinoma of the prostate, and bony lesions in the pelvis and ribs were interpreted as probably prostatic in origin.

On May 18, 1954, a modified Gordon Murray procedure was performed. At operation a mass was encountered in the dome of the bladder. This was excised and a suprapubic cystostomy done. Microscopically this was thought to be metastasis from the rectal lesion. Postoperatively the patient developed a fecal fistula, noted on the twelfth postoperative day. Because of poor general condition a colostomy was not done, and the fistual filled in gradually, finally healing in two months.

Comment.—Trans-sacral resection was elected in this elderly patient because of the presence of a second carcinoma with metastases. This man would undoubtedly have been benefitted by a colostomy, but the fistula eventually healed. The patient died one year postoperatively.

Case 4.—S. T., a man aged sixty-five, was admitted to Minneapolis Veterans Hospital January 16, 1954, for treatment of carcinoma of the rectum at 6 cms., proven by biopsy. The patient was confused, disoriented, totally incompetent and incontinent and had been under treatment for arteriosclerotic cardiovascular disease with fibrillation, and cerebral arteriosclerosis. Examination revealed a disoriented, senile, compensated cardiac patient with auricular fibrillation. No distant metastases were demonstrated.

On February 3, 1954, a modified Gordon Murray procedure was performed. The submitted specimen revealed adenocarcinoma of the rectum with metastases to the lymph nodes. Postoperatively the patient developed atelectasis and had drainage from the upper margin of the posterior wound, but no fecal fistula was demonstrated. Following operation, the mental condition improved slightly and the patient was continent of feces.

The patient was transferred to a mental hospital for further care. Follow-up indicates that he died one year later of arteriosclerotic heart disease. Autopsy failed to show recurrent tumor.

Comment.—Because of the mental deterioration of this patient, it seemed advisable to attempt a resection that would preserve sphincter function. Difficulty in colostomy care contraindicated the Miles procedure.

Discussion

In Gordon Murray's original report of fifteen cases, five were followed by fecal fistula although all maintained good sphincter control with eventual healing of the fistula. In no case did he feel justified in performing a diverting colostomy.

In this present group, fecal fistula occurred in two patients, one in whom a colostomy existed prior to the procedure. Colostomy was considered for the second patient, but this was not done. Experience with this limited group suggests that a diverting colostomy probably should be done in most instances.

The original procedure has been modified to include an abdominal stage in order to achieve more adequate, wider resection. Neither the original nor the modified operation is the procedure of choice in the majority of rectal lesions but is cited as a useful tool in very selected patients.

Summary

1. A modification of the procedure described by Gordon Murray is described.

2. Four illustrative cases are cited.

3. This procedure is useful in selected cases where retention of sphincter control is mandatory.

4. The abdominopresacral resection here described is not intended to replace more conventional methods in the usual patient.

Discussion

Dr. R. J. Tenner: I enjoyed Dr. Utendorfer's presentation very much and agree with him that the combined abdominal perineal resection always raises the two problems of urinary and sexual complications. By preserving the sphincter muscle as in the Gordon Murray procedure, many of the sex and urinary complications can be avoided. In view of the increase in the younger group with carcinoma of the rectum, this is a real and important consideration.

Dr. Howard M. Frykman: I have had no personal experience with this particular procedure, but I would think that it might have a definite place in obese patients, with lesions at the recto-sigmoid or upper rectum. In these individuals, a low end-to-end anastomosis done through the abdomen is extremely difficult technically because of the obesity. It also might be used in palliative procedures done for adenocarcinoma of the rectum in which hepatic or other distant metastases are present. When there is no hope of cure because of inoperable metastases, one hesitates to establish a permanent colostomy if it is technically feasible to avoid it. With the high incidence of postoperative perineal fistulas, however, one might be reluctant to attempt this procedure. Even though many of these perineal fecal fistulas heal spontaneously in time, it is a distressing complication to both the patient and the surgeon when it does occur.

Dr. L. F. Sherman: Use various procedures selectively: (1) Group of old patients, and those with mental aberrations where sphincter control is very important because patient cannot care for colostomy; (2) Below the middle valve of Houston the occasional operator should stick to combined abdominal perineal procedure; (3) Selected early lesions (carcinomas) without local extension above the middle valve of Houston (7-8 cm.) to 12 to 14 cm. are ideal for resection by "pull-through" procedures, whether by the classical Bacon-Babcock procedure or the Swenson perineal anastomosis depends upon the operators experience.

Dr. R. W. Utendorfer (closing): I should like to thank the discussants for their comments. I am certain that we all agree that the Gordon Murray procedure or its modification has only limited application. It is cited here as useful in certain selected instances and has been a satisfactory procedure when performed for these indications.

Intrapleural Use of Nitrogen Mustard in Malignant Pleural Effusion

Excessive accumulation of pleural fluid is a troublesome accompaniment of malignant tumors of the lungs and pleural surfaces. This paper describes the intrapleural instillation of nitrogen mustard for controlling such effusion. Two-thirds of a group of 28 patients received benefit from this treatment.

PLEURAL effusion frequently is associated with malignant tumors involving the lungs and pleural surfaces. Occasionally, such an effusion remains small and relatively asymptomatic for comparatively long periods. Usually, however, it is a problem of major symptomatic importance to the patient. Dyspnea, cough, thoracic discomfort and pain associated with thoracentesis may be the only symptoms of the malignant lesion in these cases. Thus, efforts to control such effusions are well directed.

Treatment usually has consisted of removal of fluid when necessary to control symptoms or irradiation of the hemithorax. When radiogold (Au^{198}) became available for intrapleural use, it represented a decided improvement in therapy. However, the cost of administering Au^{198}, in addition to the radiation hazard attending its use, made it desirable to find a different agent that might be equally effective.

In 1948, Karnofsky and associates[1] first reported the intrapleural administration of nitrogen mustard (methyl-bis [β-chloroethyl] amine hydrochloride). Since then, others[2-4] have documented its use. Bonte and co-workers[5] obtained satisfactory control of pleural effusion with nitrogen mustard in 66 per cent of their patients, which equaled their success with Au^{198}.

We wish to present the results obtained with the intrapleural administration of nitrogen mustard at the Mayo Clinic.

Methods

Patients included in this study had malignant cells in the pleural fluid plus a clinical history suggesting a malignant tumor or had a proved malignant tumor with associated pleural effusion for which no other cause was demonstrated. Whenever possible, use of nitrogen mustard was delayed until some knowledge was gained as to the rapidity with which fluid was forming. If treatment was to be instituted, leukocyte and platelet counts were checked, after which thoracentesis was done in the usual manner, utilizing a three-way stopcock and removing as much fluid as could be done easily. Sufficient fluid for purposes of dilution was allowed to remain. Through the stopcock, a freshly prepared solution of nitro-

gen mustard was injected after it was determined that the tip of the aspirating needle was still in the pleural space. The dose was 0.4 mg. per kilogram of body weight. The patient was instructed to change position frequently during the following hour in an effort to expose as much of the pleural surface as possible to the action of the nitrogen mustard. When it became obvious that the patients usually experienced nausea after this procedure, chlorpromazine or a related drug was given just before thoracentesis.

If pleural fluid rapidly reaccumulated, thoracentesis was repeated twenty-four to forty-eight hours later. This reaccumulation presumably resulted from pleural irritation produced by the nitrogen mustard. Otherwise, thoracentesis was not done routinely after treatment. In a number of instances, roentgenograms of the thorax made one or two days after treatment suggested that considerable pleural fluid was present. However, appropriate roentgenograms made with the patient in the lateral decubitus position frequently demonstrated that this density represented primarily a pleural reaction or loculated fluid. Thoracentesis yielded little fluid in such instances.

Results

A total of fifty-five patients was treated in the manner just described. This group included thirty-nine females and sixteen males. The primary malignant tumors encountered are listed in Table I. Carcinoma of the breast accounted for almost 50 per cent of the total.

It is difficult to evaluate this form of treatment. Three categories of patients were eliminated from the study (Table II). Because the rate of formation of pleural fluid varies greatly in different patients, it was required that the history contain sufficient data to allow us to estimate accurately how rapidly fluid was forming; in the absence of such data, the patient was excluded from the study on the basis that we had no pretreatment information with which to compare posttreatment results. Merely determining how often thoracentesis was necessary after treatment was not considered adequate grounds for estimating the efficacy of treatment. Thus, six patients were excluded because of insufficient pretreatment data. Patients living less than one month after treatment constituted the second category excluded from the study; there were eight such patients. Three additional patients were lost to follow-up. Thus, seventeen patients were excluded because

of insufficient data. The third category consisted of ten patients who were omitted from this study because other forms of treatment, such as the use of hormones or radiation, that might have been a factor in the control of fluid had been used simultaneously. Most of these patients had carcinoma of the breast.

A total of twenty-eight patients remained for study (Table II). In twelve (43 per cent), the instillation of nitrogen mustard into the pleural space was of definite value. These patients either did not require thoracentesis for significant periods or the number was reduced significantly. An additional seven patients (25 per cent) probably received benefit. In these patients, fluid still re-formed but at a slower rate, or the benefit was of short duration. The remaining nine patients (32 per cent) did not receive any benefit. When only patients with carcinoma of the breast were considered, the results were similar. Three patients received more than one dose of nitrogen mustard. In one, the first treatment was not successful whereas the second one was; in the second patient, both administrations of nitrogen mustard were definitely beneficial; in the third patient, the first treatment was of a definite benefit but the second and third treatments were without benefit. None of the small group of patients with lymphoma were benefited.

Usually, the patient experienced nausea and vomiting within one hour and a pleuritic type of pain for one to three days after the injection. Hematologic complications were not encountered when the standard dose of 0.4 mg. per kilogram of body weight was used.

Comment

The results thus far have approximated those obtained previously at the clinic[6] with Au^{198} in the control of malignant pleural effusion, and they have encouraged us to continue use of nitrogen mustard in place of this agent.

The method by which nitrogen mustard accomplishes control of effusion is not altogether clear. Presumably, its cancerocidal action is important. However, it also produces chemical pleuritis that may alter the pleural surface in such a way as to reduce the formation of fluid or may lead to adhesive pleuritis that precludes the re-formation of pleural fluid. It is on such a basis that Chambers[7] has used with success a noncancerocidal but irritating agent such as talc in the pleural space to prevent recurrence of pleural effusion. We have chosen to continue using nitrogen mustard because it does have cancerocidal properties and because it has not caused significant complications, but we emphasize its potential for producing obliterative pleuritis. For this reason, as already indicated, we now remove as much pleural fluid as possible twenty-four hours after the instillation of nitrogen mustard unless free fluid is not evident. In those patients who form large amounts of pleural fluid, we have been utilizing an intercostal catheter to drain the pleural space, instilling the nitrogen mustard and, after twenty-four hours, reapplying constant suction until the pleural space is empty, as described by Taylor.[8] This procedure has the disadvantage of requiring the patient to be in the hospital for a longer period.

Summary

A group of twenty-eight disabled patients with pleural effusion caused by malignant tumors were treated by the intrapleural instillation of nitrogen mustard. A total of 43 per cent were definitely benefited, 25 per cent probably were benefited, and 32 per cent were not helped.

Soft Tissue Injuries of the Hand

DONALD P. SMILEY, M.D.
Saint Paul, Minnesota

THERE ARE several fundamental principles that must be followed in the treatment of hand injuries.[1]

First of all—the history of the wound, including the time, type of instrument causing the wound, and the nature and extent of first treatment, must be determined accurately. The open wound and injured tissues must be protected from further injury and from secondary contamination. An accurate determination of the extent of injury must be made. All devitalized tissue should be excised by sharp dissection in a methodical manner in order to transform the open wound into a surgically clean wound. One should use good judgment in debridement and be particularly conservative in debriding the skin. All exposed vulnerable structures such as tendons, nerves, joints, and bones should be closed over and the wound as a whole closed.

The causes and prevention of crippling of the hand should be uppermost in one's mind when attempting treatment. The common types of crippling seen as a result of hand injuries have been thoroughly reviewed by Bunnell[2]: stiffening in the position of non-function, flexion contractures, skeletal malalignment, and trophic disorders.

Stiffening in the position of non-function with loss of opposition of the digits is due to three main factors: swelling, immobilization, and allowing the hand to remain in the position of non-function. When the hand is immobilized, only the injured digits should be immobilized. The position of function is well known, but it bears repeating: the wrist is dorsiflexed about 30°, the finger joints are in moderate flexion, the metacarpals form an arch, and the thumb is in moderate opposition. In this position the tips of the fingers all point toward the carpalnavicular; this point should always be kept in mind when splinting a finger or fingers. The wrist is the key joint of the hand and the proximal finger joints are the key joints of the fingers. When the wrist is dorsiflexed, the hand assumes the position of function; when the metacarpophalangeal joints are flexed, the fingers "unclaw." The position of nonfunction is preventable by proper immobilization of these two joints. If the fingers must be immobilized they should not be in extension or in forced flexion.

Flexion contractures are the common sequelae of wounds, infections, and burns. The infected open wound is the most common cause of flexion contractures.

Skeletal malalignment from either malunion of fractures or unreduced dislocations disturbs the finely balanced function of the muscles, joints, and tendons of the hand.

Vasomotor dystrophies—such as Sudek's atrophy or causalgia—may result in lowered nutrition, pain, lessened motion, and fixation in poor position.

Initial Treatment of Open Injuries

On preliminary inspection, the location, extent, state of cleanliness, and type of wound are noted. A sterile dressing is applied and physical examination for bone, nerve, and tendon injury is performed, thus a clinical diagnosis is made before the patient is sent for x-ray or to the operating room. If antibiotics or tetanus toxoid (or antitoxin) are indicated, they may be given at this time.[3] We do not use prophylactic antibiotics routinely.

Definitive Treatment of Open Injuries

The initial preparation is done in the operating room with the use of either brachial block or general anesthesia. The hand and forearm are shaved; thorough cleaning for at least ten minutes is done with a detergent while a sponge is held over the wounds to minimize contamination. The wounds are not scrubbed with a brush or inundated with alcoholic solutions. Copious saline irrigation is carried out throughout the preparation. If there is contamination with grease, preliminary cleansing of the hand with ether may be necessary.

A good tourniquet is an absolute necessity. The area is then approached through the laceration. If necessary, the lacerations are extended for adequate exposure, being careful of crossing skin creases. The area is debrided by sharp dissection, saving as much skin as possible. Nerves are not debrided, as a general rule.

Following debridement, the extent of the wound is evaluated and the plan of repair determined. On rare occasions where adequate debridement cannot be done or the hand is badly traumatized and contaminated, the wounds may be packed lightly with fine mesh gauze and a secondary closure performed within ten days.[4] Generally, a primary closure may be done within twenty-four hours in a relatively clean, incised wound and within twelve hours, in a crushed wound in which adequate debridement can be done. If there is skin loss, the area should be closed with a split-thickness skin graft, if at all possible.

Tendon Injuries

In general, if the skin can be closed and the wound is clean, and not over four hours old, primary tendon suture (using 0000 silk or a pull-out wire) may be done by the experienced operator with adequate facilities and assistance. If the viability of the skin is questionable or if the hand cannot be mobilized in three weeks, delayed suture or a tendon graft should be used. A lacerated tendon adjacent to a fractured bone would not be sutured primarily, because it will very likely become adherent. To date, the results of primary repair are not significantly better than delayed repair, even in the most experienced hands. It is not worth while performing a primary repair if there is any question, whatsoever, of the tendon becoming adherent.

Flexor Tendons

The end results in repair of flexor tendon injuries, particularly within the osseofibrous tunnel of the fingers, still presents a rather unhappy picture. Flynn[5] presented the results of 401 tendon injuries seen over a two-year period in 1953; 51 per cent (of eighty-nine cases) showed poor results in repair of flexor tendons within the sheath and 32 per cent (of forty-one cases) gave poor results in repair of the extensors within the fingers.

The simplest method of suture is a double right-angled 0000 silk suture;[4] a pull-out wire and fine silk approximating sutures may also be used.

If the profundus tendon is lacerated beyond the insertion of the sublimis tendon, one may perform a primary repair if conditions are ideal. The profundus may be advanced and sutured to the bone or to the stump of the tendon distal to the distal interphalangeal joint. If the profundus is lacerated at the decusation of the sublimis tendon a primary interphalangeal tenodesis or secondary interphalangeal arthrodesis may be performed. If both sublimis and profundus tendons are lacerated in "No Man's Land" (proximal finger crease to distal palmar flexion crease), a secondary graft or reconstruction should be done. If the sublimis tendon alone is lacerated within the sheath, no repair is needed because early motion will maintain profundus excursion and satisfactory function will be obtained. When the sublimis tendon is lacerated in the palm, no repair is indicated. The treatment of laceration of both the sublimis and profundus tendons in the palm will depend upon the position of the fingers at the time of injury.[6] If the finger was in flexion at the time of injury, a secondary graft is performed since the juncture of the tendon ends, with the finger in the functional position, would be within the flexor sheath distal to the metacarpophalangeal joint. If the finger was in extension at the time of injury, the juncture of the tendon ends will lie in the middle of the palm with the fingers in the position of function; therefore the profundus alone is repaired.

Extensor Tendon Injuries

One of the most common injuries about the distal portion of the extensor tendon of the finger is the so-called mallet finger. This is usually a closed injury resulting from avulsion of the conjoined tendon from the base of the distal phalanx of this finger. We prefer to treat these by closed means with a cast or splint; on occasion, particularly with undependable patients, one may use a Kirschner wire for fixation. The finger must be held with the distal interphalangeal joint in hyperextension and the middle interphalangeal joint flexed.

A laceration in the region of the proximal interphalangeal joint of the finger usually results in severance of the central extensor slip and displacement of the lateral bands. This type of injury results in the so-called boutonniere deformity with flexion of the proximal interphalangeal joint and extension of the distal interphalangeal joint because of volar displacement of the lateral bands and retraction of the central extensor slip. One must repair the central extensor slip and may need to approximate the lateral bands.

Laceration of the extensor tendon about the proximal phalanx results in flexion deformity of all the phalanges. The extensor hood and all the

extensor apparatus, including the intrinsic muscle insertions, should be repaired. This is a very serious injury and frequently results in considerable disability even though repair is performed.

When the long extensors of the fingers are lacerated over the dorsum of the hand there is very little retraction and suture is very simple. These tendons interdigitate so freely over the dorsum of the hand that they can be approximated readily by dorsiflexion of the wrist; one need use only fine approximating sutures and a splint for treatment of this injury.

The Thumb

The long flexor of the thumb has no vinculae and no lumbricale muscle; threfore, retraction will be great following a laceration. This construction offers one advantage in that the tendon can be lengthened easily from a point far proximal to the laceration. If the long flexor is lacerated in its distal portion, it may be advanced and sutured. Repair at the level of the metacarpophalangeal joint and proximal phalanx should be avoided since this is the constricted area of the sheath near the sesamoids; if the tendon is lacerated at this level, it should be lengthened at the wrist or advanced and sutured.

Repair of lacerations in the thenar area is particularly hazardous because of the danger to the important motor branches of the median nerve. When the nerve is intact, a secondary repair using a graft should be performed. If the tendon and nerve are lacerated, both should be repaired.

The long extensor of the thumb retracts considerably when cut, but it can be repaired primarily or secondarily without too much difficulty. The abductor pollicis longus is also easily repaired; it is important that this tendon be repaired because it is a stabilizer of the carpo-metacarpal joint of the thumb.

Postoperative Care of Tendon Injuries

The hand should be splinted as close to the functional position as possible; firm and even pressure should be maintained.

After repair of flexor tendon injuries, the hand is splinted with the wrist in about 45° palmar flexion and the fingers in mild flexion for three weeks; at the end of that time the splint may be removed twice a day for soaks and mild active exercises. After the fourth week, the splint is discarded entirely and exercise is continued.

In extensor tendon injuries, the hand is immobilized with the wrist in about 30° dorsiflexion and the fingers in mild flexion; the fingers are not splinted in full extension at any time. Extensor tendon repairs are immobilized four to five weeks.

Nerve Injuries

The injured nerves should be identified and sutured if possible. If the nerve cannot be sutured it should be tagged with fine wire and a secondary graft performed. Sutures of 00000 silk through the epineurium are used for approximation and the nerve should not be sutured under tension. It is a worthwhile effort to locate and suture the digital nerves out to, or even beyond, the proximal interphalangeal joint.

Injury to the Skin

If there is any question as to the viability of the skin, the tourniquet test may be used: Upon release of the tourniquet, that skin which does not show a marked blush, but remains white or cyanotic, should be excised. It is advisable to resect skin that is questionable rather than to try to salvage portions that have no blood supply. These areas should be covered immediately, if possible, with split-thickness skin grafts. If there is extensive skin loss, particularly over the palm or dorsum of the hand, a pedicle graft may be required.

Fingertip Amputations

Generally, we make every effort to maintain as much length as possible in the thumb and index fingers. If the bone is not exposed at the tip, one may cover it with a split-thickness skin graft. When the bone is exposed, one should use a full-thickness skin graft. It is difficult to maintain pressure over the end of a finger; this can be attained by leaving the sutures long and tying them over a piece of moist dental cotton. Nerves should be excised so that they retract well away from the site of amputation. Tendons should not be sutured over the end of the bone at any time. It must be remembered that grafting of finger tips prolongs the healing time; in the elderly patient or heavy laborer, shortening of the finger by plastic amputation, leaving the scar on the dorsum of the finger with a long volar flap may give quicker wound healing.[7] This type of repair also results in more normal sensation at the end of the finger and the tough volar skin withstands trauma better than a graft.

Diagnosis of Hodgkin's Disease

By Bone Marrow Aspiration

The section method of bone marrow study in contrast to the usual smear technique provides a higher percentage of positive results in the diagnosis of Hodgkin's disease. When the method of Dr. Emil Schleicher is used, it makes the tissue easier for the pathologist to identify and study.

THE DIAGNOSIS of Hodgkin's disease is usually suspected from the clinical picture including among other things weakness, fatigue, weight loss, fever, enlarging lymph nodes, splenomegaly, hepatomegaly and anemia. The suspicion is confirmed by removal and study of an enlarged lymph node which shows the typical pattern of Hodgkin's disease. In a number of instances, however, this procedure is not adequate to completely evaluate the case and to establish the best therapeutic regime. First, peripheral easily accessible nodes may not be enlarged and only thoracic or abdominal surgery could yield the necessary pathologic pattern for the diagnosis. Second, there may be a question of extent of the disease beyond a single group of nodes and again more extensive surgery needed to evaluate the problem in individual cases. Third, a vague symptom complex may not suggest Hodgkin's disease but the over-all process may be one of systemic non-specific disease. In such instances as these, bone marrow biopsy is recommended as a relatively easy method of gaining much needed information in diagnosis, classification, treatment, and prognostication of problem patients.

Review of the literature reveals an interesting divergence of opinion concerning the value of bone marrow study in Hodgkin's disease. Wintrobe[1] in his clinical hematology text states that the chief value of bone marrow in conditions affecting lymph nodes is to rule out leukemia especially the aleukemic form. The most constant

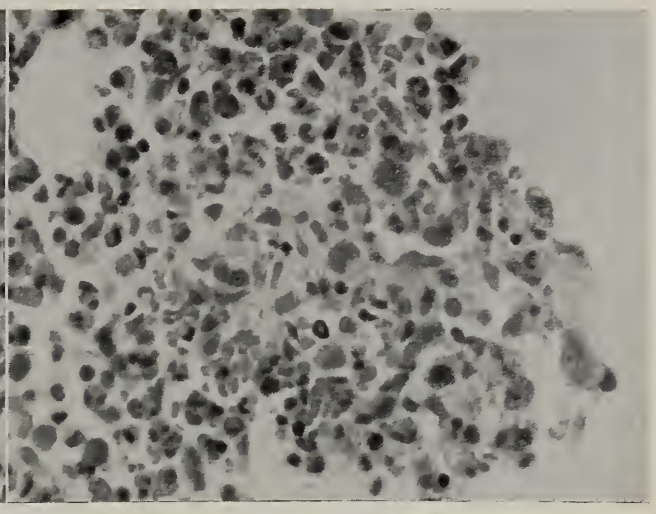

Fig. 4. Early reticulum change to malignancy (*large cells in center*). The early proliferation has nonetheless stimulated a hyperplastic reaction of eosinophils (*upper center*).

WAYNE A. CHADBOURN, M.D.
Minneapolis, Minnesota

Dr. Chadbourn is Associate Pathologist at the St. Barnabas Hospital, Minneapolis, Minnesota.

Inaugural thesis presented before the Minneapolis Academy of Medicine December 15, 1958.

feature in Hodgkin's disease according to the same author is myeloid and megakaryocytic hyperplasia. There may be a slight left shift of myeloid series or slight monocytosis or eosinophilia. Megakaryocytes may show immaturity and "naked" nuclei. A number of authors concur in this belief[2] that only a non-specific picture exists in this disease. Limarzi[3] especially influenced this field with a large series of cases without definite bone marrow changes.

A few authors,[2,4,5] report cases in which Reed-Sternberg cells were identified in the marrow. Sunberg[4] reported one patient on whom granulomatous lesions were seen in bone marrow sections but only after an "extremely diligent search" was a single Reed-Sternberg cell found in smear preparations.

The incidence of bone lesions in reported series is highly variable depending on the method of study. If only clinical evidence is used, an incidence of 8.3 per cent is reported by Steiner,[6] but systemic examinations at autopsy have revealed bone lesions in 50 per cent. Ewing[10] states that it is rare that a thorough search at autopsy fails to disclose some deposit in bone marrow. Steiner[6] studied easily accessible bones in fourteen cases of Hodgkin's disease and found lesions in 78.6 per cent, the sternal marrow containing lesions in 63 per cent of his fourteen cases. The same author states that there is no basis for the impression that skeletal lesions occur as a late manifestation of Hodgkin's disease.

The histological pattern of Hodgkin's disease

varies widely in different cases and even varies in multiple nodes from a given case. Bell[7] lists the following as features considered distinctive of Hodgkin's disease: increase in number and size of reticulum cells, giant cells of the Reed-Sternberg type, areas of fibrosis, obliteration of the sinusoids, eosinophilic leukocytes, and sometimes areas of necrosis. The essential feature is the overgrowth of reticulum cells with crowding out of the lymphocytes usually with some cells typical of the Reed-Sternberg type. Distinction into three types has been advocated in some areas.[8] The granulomatous type is the usual most commonly recognized form. The paragranulomatous lesion is a relatively benign type seen in about 10 per cent of cases and a "true neoplasm" of the sarcoma type is a more malignant form. All three blend together to a certain degree in a given case and all have Reed-Sternberg cells. The tendency of the three to intermingle tends to de-emphasize the value of this division, but Jackson and Parker[8] insist that any description including all three as a single form is inaccurate and of little value, so I have mentioned their classification and now I hope I have met their requirements and may again speak of the over-all picture of Hodgkin's disease without hurting their feelings or my own.

Because of the success of the section method of bone marrow study as described and refined by Doctor Emil Schleicher,[9] it seemed that a number of cases studied showed definite evidence of Hodgkin's disease in our bone marrow material. This study was, therefore, undertaken to demonstrate the value of such type of marrow study. It would appear that comparison of the bone marrow smear material with that of the unit in section shows that the hyperplastic reticulum does not easily separate out of the unit, and, therefore, is not free to be smeared out as are the developing myeloid and erythroid series or other free flowing cells of the bone marrow. The methods of aspiration, separation of units, preparation and staining have all been well documented and do not need repetition here.[9]

All cases were taken from the Tumor Registry of St. Barnabas Hospital from the years 1953 to November 1958 and include only those cases in which Hodgkin's disease was diagnosed or seemed a likely possibility.

Thirty-one such cases were found in our Registry. Of these thirty-one, two were patients with vague central nervous system symptoms whose bone marrow showed reticular hyperplasia of a type suggesting Hodgkin's disease. Neither of these have had node biopsies or any further study suggesting Hodgkin's disease and are not used. Three cases had the symptom complex suggesting reticuloma, all three had bone marrows with reticular hyperplasia but not diagnostic Reed-Sternberg cells. Because these three are lost without follow-up, node biopsies, or clinical course, they are also not considered in our series.

Twenty-six cases remain which are proven Hodgkin's disease by lymph node biopsy, major surgical specimen, or autopsy. Of these, twenty-two had bone marrow aspiration performed in the course of their diagnostic work-up. Fifteen of the twenty-two showed changes in the sections compatible with Hodgkin's disease, four had changes considered to be probable Hodgkin's disease; that is, reticular hyperplasia, eosinophilia, fibrosis, et cetera. Three cases showed no changes of Hodgkin's disease.

The dominant histologic change in Hodgkin's disease is a pathologic activation of the reticular cells of the reticulo-endothelial system. It is reasonable to expect that a tissue as rich in reticulo-endothelial tissue as the bone marrow would be commonly involved in this disease. If the bone marrow unit is studied in paraffin sections as are all other pathologic materials, the true pattern can be identified by characteristics we have learned to recognize in other tissue studies. Criteria for the diagnosis of Hodgkin's disease in a lymph node, spleen, or other organ then can be transferred to the bone marrow and familiar pathologic landmarks may be seen in their true perspective. Thus the anatomical pathologist need not feel off base or on unfirm ground when looking at bone marrow section material, as he may well be when looking at bone marrow smears, stained differently and with no relationship from one cell to the next.

The material presented in this report, of course, covers a wide range of the disease spectrum known as Hodgkin's disease. The custom of medical practice is to diagnose Hodgkin's disease by biopsy of lymph node and this series is no exception, since all cases were diagnosed by this means. The typical criteria previously mentioned were present in varying degrees and in varying stages. The bone marrow study in these cases was done in the same year in eleven cases and more than a year after the node biopsy in eleven cases.

The bone marrow changes include the changes

previously outlined but center mainly for diagnostic purposes about the hyperplastic reticulum cells. Photomicrograph number one shows a typical low power view of the hyperplastic marrow surrounding a nodule of dense cellular proliferation which even at this magnification has malignant characteristics.

A closer look at the nodular process (photomicrograph number two) shows a number of malignant reticular cells. Note the closely packed syncytial nature of the reticulum with Reed-Sternberg cells and scattered lymphocytes and eosinophils caught in their mesh. It is not difficult to see why cells such as these do not break free in smear preparations. Photomicrograph number three shows a typical Reed-Sternberg cell with its large multilobulated or indented nucleus, a definite chromatin net and prominent nucleolus. The abundant cytoplasm may be granular, flaky, or amorphous.

In less involved areas, the involvement of the marrow may be by other cells not of diagnostic character but usually altered by the disease process. Lymphocytes and eosinophils have already been mentioned as increased in number. Correspondingly there may be megakaryocytic hyperplasia as a prominent feature. These cells, though large, are distinguished from Reed-Sternberg cells by clumping of chromatin in a small nucleus with no nucleolus. The cytoplasm varies with the stage but should not be confused with Reed-Sternberg cells.

Normoblastic hyperplasia takes place early in bone marrow irritation and later as the marrow is crowded out the remnants of normoblasts may be seen in small clusters. Similarly, plasma cells may increase usually as an increased perivascular cuff.

The last photomicrograph, number four, shows an area of early minimal malignancy in bone marrow. Only a few abnormal cells are seen here without characteristics of Reed-Sternberg cells but definitely abnormal reticulum suggesting changes toward this specific cell type.

From the above material, it appears that Hodgkin's disease can be diagnosed from bone marrow material. An attempt has been made to show that all portions of the marrow take part in the irritation and stimulation of the marrow including myeloid, lymphoid, erythroid, eosinophilic, plasma cell and megakaryocytic series. The many reports in the literature of inability of bone marrow to be of assistance in this disease may be due to the universal tendency to depend on smears of buffy coat layer. If sufficient material is aspirated with an adequate number of marrow units or particles to give a good cross section of the actual marrow organ, then pathology in that organ will be demonstrated. Many short cut methods using only a few units, letting the units clot in red blood cells, thromboplastin, or fibrin; taking only one section rather than a number of skip serial type sections, putting what few units are available through mechanical preparation rather than getting them into paraffin by careful hand methods; staining in routine tissue procedure rather than in separate stains—all these with other things explain the disappointing results reported with sections. The methods perfected by Doctor Schleicher, coupled with his ability to interpret changes in marrow sections to a degree not usually attained by most of us, have made it possible to establish patterns of disease in bone marrow. One such pattern has been presented as consistent with Hodgkin's disease in other tissues.

The value of the section method of bone marrow study has been mentioned earlier. First, bone marrow may aid in diagnosing a patient without enlarged peripheral nodes but with mediastinal or hilar nodes, or an enlarged spleen or liver. Second, the extent of disease beyond a single group of nodes may be determined by bone marrow study. This we know to be of value now that radical surgery is contemplated if the disease is localized or of aid to the roentgenologist in selecting his sites of therapy. Thirdly, bone marrow can aid in diagnosis of reticuloma in a vague symptom complex. A fourth area of use of bone marrow study may be to follow up effect of therapy in a case with previously proven dissemination of disease.

An accumulation of cases studied by node biopsy and bone marrow aspiration including adequate emphasis on the section material may lead to clues on the mode of origin of the disease, its method of spread, or its limiting factors. The use of bone marrow material for study opens an easily accessible tissue for repeated follow-up and investigation.

Summary

The section method of bone marrow study in cases of Hodgkin's disease has been presented. Of twenty-two cases of Hodgkin's disease proven by lymph node biopsy, fifteen, or 68 per cent, showed definite changes of Hodgkin's disease in the bone marrow. In addition four had changes suggestive

of this diagnosis, and three showed no evidence of the disease.

The section method of bone marrow study is, therefore, recommended as an extremely useful tool in the proper evaluation of Hodgkin's disease.

Addendum

Since summarizing the above material, four additional cases of Hodgkin's disease have been diagnosed by lymph node biopsy. Bone marrow done in all four shortly after the node biopsy revealed Reed-Sternberg cells in marrow units of three of the four. In two of the cases, at least two lymph node groups were clinically involved but in one case only a single group is known to be involved.

Discussion

Dr. Emil M. Schleicher.—My work on diagnostic marrow patterns of Hodgkin's disease began in 1945. Some of the marrow patterns of this clinical entity have just been presented by Doctor Chadbourn. I am sure that you are in agreement with the statement of Doctor Chadbourn that "the patterns are compatible with those seen in other organs." I am aware that my method of examining a marrow sample entails a lot of work but it seems to me that the high percentage of positive samples more than compensates the effort.

I wish to compliment Doctor Chadbourn for presenting to this assembly a very informative and well illustrated paper, that I am sure, has fixed clearly in your mind the fact that Hodgkin's disease may be detected by marrow biopsy.

Dr. N. H. Lufkin.—It would appear that Doctor Chadbourn is the first to show that the clinical use of sternal puncture is comparable to postmortem study of the bones as an effective method of establishing the presence of bone marrow involvement in cases of Hodgkin's disease.

Much credit for the favorable and logical statistical results of the study is probably owing to selection of the Schleicher method to obtain and prepare the bone marrow samples. It is recalled that the average specimen obtained by this method is equal to a tissue mass one centimeter square and one millimeter thick. Such a specimen, serially sectioned, yields a relatively vast tissue area for study, and its examination and interpretation present no greater difficulties than do lymph node sections.

Dr. Robert A. Green.—The finding of such a high percentage of positive bone marrow aspirations in this group of cases of Hodgkin's disease is rather surprising. Generally speaking, bone marrow biopsy in this disease is not so highly rewarding.

It is difficult to reconcile the known high five and ten year survival rates of clinical stages I and II with the finding of a positive bone marrow biopsy since the latter must reflect widespread involvement of the reticuloendothelial system. By definition such cases would fall into the clinical stage III in which five year survivals are very low and ten year survivals almost zero. I wonder if clinical grouping of the cases reported might not reveal that they were largely far advanced, that is, stage III cases, and thus explain the high incidence of positive marrow aspirations.

I should like to call attention briefly to another technique useful in the diagnosis of Hodgkin's disease, that of lymph node imprint. The cut surface of a freshly removed, unfixed node is simply pressed several times on a clean glass slide. Slight squeezing will result in more cells in each imprint. The slide is dried quickly in air and stained in the usual way for blood smears with Wright's stain. Reed-Sternberg cells with their characteristic large nucleoli may be readily identified in this simple but beautiful type of preparation.

Dr. Benjamin Bofenkamp.—Would it be feasible in using this aspiration technique which you so well outlined, to employ it for needle biopsy of lesions thought to involve the subcarinal lymph nodes of the lung?

Dr. R. S. Ylvisaker.—Is there any difference in sites of biopsy—should it all be sternal, or should other bones be biopsied?

Dr. W. A. Chadbourn (closing).—Doctor Green has emphasized the high percentage of patients with positive bone marrow. This is partially answered by the fact that eleven or one-half of the cases had the bone marrow biopsy more than one year after Hodgkin's disease was first diagnosed and the longest interval was six years. The other four cases with positive findings were biopsied, both node and marrow, the same year, two of these four also came to autopsy the same year.

The needle biopsy technique would not in my estimation be of help in diagnosing subcarinal lymph node disease. In bone marrow biopsy we aspirate from between the tables of cancellous bone and do not enter the pleural or mediastinal space. These latter areas are too loaded with large vessels, heart, and lungs to blindly seek a lymph node here.

A Surgeon's Progress

A surgeon who has practiced his art in Minnesota for forty years reminisces about some of his experiences and about the people and circumstances that molded his life and surgical progress.

Read at a special meeting of the Saint Paul Surgical Society, St. Paul, Minnesota, March 16, 1960.

WALTMAN WALTERS, M.D.
Rochester, Minnesota

From the Section of Surgery, Mayo Clinic and Mayo Foundation. The Mayo Foundation, Rochester, Minnesota, is a part of the Graduate School of the University of Minnesota.

THIS OCCASION I shall always remember with the greatest of pleasure and with a feeling of deep gratitude that the Saint Paul Surgical Society would arrange a meeting honoring me, one of your honorary members, and one of the many surgeons who have admired the virility of your society, the scientific contributions of your members, and the devoted work of your secretary, Dr. William Hartfiel.

It is customary at the Mayo Clinic to write a reminiscence of one's experiences as a member of the staff. It is hoped that everyone who is nearing retirement will begin assembling material in order to be able to write it up and have it available for reading at the time of retirement or shortly afterward. Since I reach the age of retirement from the clinic this fall, I have been gathering the data and reporting on my experiences during a most pleasant three weeks spent in the Tucson area. I mention this undertaking because I recommend that all of you do the same thing, but do not wait until you reach retirement age.

Reviewing and recounting the interesting experiences I have had, first as a Fellow in Medicine

in the Mayo Foundation, then as a Fellow in Surgery in the same institution, and later as a member of the surgical staff of the Mayo Clinic have brought back many pleasurable moments. Indeed they have brought back memories of minor events, many of which have given me the same feeling of warmth and pleasure that events of greater magnitude have. Many of these memories have to do with friends met along the way in medical and surgical associations, colleagues whose interests in similar fields led to closer friendship in the environment of examining rooms, hospitals, operating rooms, research laboratories, and, of course, the library. To a medical man or surgeon these all tie in with that enveloping feeling of pleasure.

A few weeks ago when I was presented with a large inscribed silver tray on my retirement from the Board of Governors of the Mayo Clinic after thirty-one years of membership and service, I tried to express briefly my appreciation of the thought behind the gift and at the same time to appraise my forty years in the Mayo Clinic and Mayo Foundation. In groping for the expression I thought of that famous book, "Alice in Wonderland," by Lewis Carroll, whose philosophy is frequently referred to, and I thought that since my experiences as a surgeon have been pleasant that they might be said to have occurred in "a wonderland of reality or actuality." By this I mean that my experience has been everything that I could possibly want and that the environment has been exceedingly pleasant. The important associations, friendly colleagues and working environment already mentioned made it possible to carry on through a surgical career in which the care of patients, teaching, clinical investigation, research, and publications were all bound together.

Weatherwise and communitywise, the environment has been pleasant too. Even though the winters are long and severe in Minnesota, nevertheless, the skies are usually bright and the sun usually shines when it is the coldest; the springs, summers, and falls are delightful. Dr. Will Mayo used to say that for all-around working weather you couldn't beat Minnesota, for you could always keep warm in the winter, and the summers were never too hot to work with pleasure even during the long hours spent in the operating room. More efficient heating and air conditioning have made it possible to govern and regulate temperatures and humidity indoors regardless of outside weather, but it is nice to live in a community and a state in which the scenery is beautiful and in which one can always enjoy lakes and rivers, hills and forests without having to drive too far or be too long away from home or from examining rooms and hospitals.

The great pleasure given me by my election to this Society as an honorary member after having been an invited guest to your meetings for many years, and that given me by my election under somewhat similar conditions to the Chicago Surgical Society are somewhat comparable. Let me go back to the root of that pleasure. I can trace it back to the two years that I attended Shattuck School in Faribault. I enjoyed those two years very much and really learned to study while there. One either studied and got one's lessons or else one walked "squad" for an hour or two, but more than that, in the classrooms there was a feeling of competition toward excellence in scholarship. In other words, if you got an A, or more than 90, your classmates, and that meant everyone, congratulated you; on the contrary, if you had a failing mark, your classmates acted as though you had run a poor race in a track meet or played a poor game on the basketball court when it was possible to have done better.

My home was in Omaha at that time, and it was easier to take the Rock Island from Faribault to Saint Paul, and the Chicago North Western to Omaha than it was to go any other way. This usually gave me an afternoon and an early evening in this city. Since the food at Shattuck was good but similar to the routine meals of all boarding schools, a steak dinner with French fried potatoes and pie à la mode was considered a real event. I usually had such a dinner at Carling's restaurant, located at that time across the street from the Saint Paul Hotel.

Walking around Saint Paul gave me a little idea of the city. In the fall of the year I hurt my knee playing football, and although the school physician was giving me good care, my father, who was an official of the Chicago North Western Railroad, thought it would be good for me to see the company's physicians and surgeons in Saint Paul. These were the partners McLaren, Ritchie, and Daugherty.

When I was going to Shattuck, I knew that I wanted to study medicine; in fact one of the reasons I went to Shattuck was to prepare for

the college of my choice. I met, therefore, the three partners, and on other occasions when I went to Saint Paul to have my knee re-examined, they all expressed a friendly interest in my work at Shattuck and my program for college and medical school. Doctor Ritchie and I became friends and years later he was one of the authors of a surgical text that I helped edit. Later his son and I became friends, meeting occasionally at meetings of this Society and the American College of Surgeons.

My relationship to the Chicago Surgical Society lay in the fact that I spent my last two years of medical school at Rush Medical College and interned for one and a half years at St. Luke's Hospital in Chicago. The surgeons on the staff at St. Luke's were members of the Chicago Surgical Society and would take us interns to an occasional meeting and not infrequently to luncheon at the University Club. After the completion of my fellowship in the Mayo Foundation and my appointment to the staff, I continued my acquaintanceship with some of the Chicago surgeons, and through them I met others. As the years passed, these friendships broadened and were extended because of mutual interest in similar fields of therapy and investigation. When I was invited to give first the Lewis L. MacArthur lecture and later the Arthur D. Bevan lecture by the Chicago Surgical Society, they were very important occasions in my life, augmented by being elected to honorary membership, as I was to this Society.

I was thrilled to be elected also to the Minnesota Academy of Medicine and to attend its meetings where I had a chance to meet many of Minnesota's distinguished physicians and surgeons —many of whom were members of this Society.

I am using these examples to illustrate the fact that in a career, friends and an environment that is pleasing are very important, and that events transpiring surrounded by such an aura remain longest in one's memory.

Important Influences

The Doctors Mayo:—Since many men have influenced my conduct, it is hard to single out particular ones among them. There are, however, four or five exceptions to this. The Doctors Mayo probably had a supreme influence on all men who had the pleasure of associating and working with them, from the standpoint of character and life, their operative skills, their philosophy of surgery, surgical teaching, and investigation. It was my good fortune to be Dr. Charles Mayo's first assistant for almost a year and a half. Since he operated three days a week, and Dr. Will, three days a week on alternate days, the first assistant for each of the Doctors Mayo had an opportunity to work as a first assistant in the second room for the other Doctor Mayo on alternate days.

These men had done practically all types of surgery in the early periods of their surgical careers and this was continuing in the 1920's. However, with the growth of the clinic work, the special fields of surgery, such as ophthalmology, otolaryngology, and orthopedic and traumatic surgery, had been taken over by specialists who had received part of their training under Doctor Will and Doctor Charlie, and the rest of it by visiting and spending time with outstanding specialists in the United States and abroad. Neurologic surgery was considered to be a part of general surgery until about 1922 when a separate department of neurologic surgery was established, headed by the late Dr. Alfred W. Adson.

Under these circumstances, the training in general surgery was received not only on the services of Doctor Will and Doctor Charlie but also on those of Dr. E. Starr Judd, Dr. Donald C. Balfour, Dr. Verne Hunt, Dr. Walter J. Sistrunk, and Dr. John deJ. Pemberton, and the services encompassed almost the entire field of surgery with the exception of the specialties which I have mentioned. For example, Doctor Will, Doctor Charlie, Doctor Judd and Doctor Hunt did urologic operations and gynecologic operations too, considering them all to be in the field of general surgery. There was, of course, a section of diagnostic urology headed by Dr. William F. Braasch and later by Dr. Gershom Thompson, but the general surgeon trained in urologic surgery was considered able to do as excellent work in this field as in the field of abdominal surgery. The same also applied to the gynecologic surgery.

The influence of our two leaders in surgery, Doctor Will and Doctor Charlie, on the remainder of the surgical staff was profound. This was due in part to the fact that all the surgeons had received most of their surgical training under them. In addition, high regard for Doctor Will and Doctor Charlie made the younger men emulate their activities, from the professional as well as the personal standpoint. Everybody attended our staff meetings on Wednesday evenings, both the early one, which

was a clinicopathologic conference, and the late one. At the clinicopathologic conference, which was limited for the most part to members of the staff, the deaths of the week were discussed; questions were raised concerning methods of therapy that might have improved the results, or open criticism was offered of failure to carry out recognized procedures if that had occurred. Happily, this did not happen often. The point I want to make is that there was free discussion of the treatment and the reason for the patient's death, supported by demonstration of the gross and microscopic pathology found both at operation and at the postmortem examination. Dr. Harold Robertson, who had been Professor of Pathology at the University of Minnesota, came to Rochester to head the Section of Pathologic Anatomy, and he did a most excellent job in the presentation of the cases at these meetings.

The second Wednesday evening meeting was a general staff meeting held in the lobby. At it, three fifteen-minute papers were presented by members of the staff on pertinent subjects of clinical interest, including the results of clinical investigation, laboratory research, and important and interesting cases.

The essayists were held rigidly to the time limit because papers of this length were presented at national meetings. One of the nicest compliments I have heard concerning presentations of clinic men was that they stuck to their time, said what they had to say, and then sat down.

Doctor Will and Doctor Charlie were always at these meetings when they were in town and occasionally would participate in the discussion of the cases at the general staff meeting. At the clinicopathologic conference they always participated in a discussion of the cases, not because it was their prerogative but because the staff members would request them to do so.

Dr. Frank C. Mann:—Doctor Mann had come to the clinic from the University of Indiana several years before I arrived. Dr. Willis Gatch recommended him to Doctor Will as a man who could develop an experimental laboratory and whose capabilities in the field of surgery and whose knowledge of physiology were such that much could be expected of him. When I arrived at the clinic Doctor Mann had made his outstanding studies on shock and later on the hepatectomized dog. These works with associated studies of normal physiology and abnormal physiology of the liver brought him international recognition. He was in charge of the experimental laboratory and when I expressed a desire to have the privilege of working with him, he welcomed me and made helpful suggestions in my start on experimental work. Associated with him was Dr. Jesse Bollman, a physiologist and pharmacologist, in addition to being a Doctor of Medicine. Bollman and I became friends, and we worked together on several problems in the laboratory, among them, the toxemias associated with pancreatic fistulas and the effect of displacement of the liver. The accumulation of bile beneath the right diaphragm after an operation for stricture of the bile ducts suggested these studies.

I spent two mornings a week in the laboratory, and Doctor Bollman made rounds with me each Sunday. We would discuss problems associated with the patients and try to see whether they would lend themselves to studies in the experimental laboratory.

These experiences were among the most beneficial training that a surgeon and a future teacher could have. They enabled me in later years to try to inculcate in fellows working with me the ability to see problems arising in the management of patients and to plan with them how the problem could be studied in the experimental laboratory.

Dr. Edward C. Kendall:—Nick Kendall's laboratory was housed in two or three rooms on the third floor of the original red-brick clinic building built in 1914. When I came to the clinic in 1920, he had already isolated thyroxin and identified it as the active principle of the thyroid gland, for which he should have received, in the opinion of many scientists, the Nobel prize. It was interesting to go up to his laboratory, as I did from time to time, because he had taken an interest in me and I was much impressed by his scientific attainments. On about half of these visits he would be using the chemical apparatus that was spread all over his laboratory. At other times he would be sitting at a desk, with a faraway look in his eye, working with pencil and paper. When I looked at the paper, I would see mathematical figures and equations with which I was unacquainted. Usually then my visit was just an in and out, as I felt sure he did not want to be interrupted, and certainly I did not want to interrupt his process of thought.

Whenever one went up to the third floor, and

especially when we went to the staff meeting room on Wednesday night, there was an offensive odor which was difficult to describe. It was explained as being the result of Doctor Kendall's boiling down hundreds of pounds of adrenal glands from cattle in order to concentrate the fluids obtained for chemical study. These studies of his at the time were looked on as the studies of an investigator and chemist, and I am sure we did not recognize the significance of them. If we had, it would not have occurred to us that Doctor Kendall would make his famous discovery of the steroid that composes the active principle of the adrenal cortex, that this substance would be applied to the treatment of disease by Doctor Hench and that as a result of these combined studies they would both receive the Nobel prize in 1950.

Doctor Plummer with his interest in thyroid diseases had suggested to Doctor Charlie, who had a large experience with the surgical removal of goiters, that Doctor Kendall might help to find the cause of goiter. Doctor Charlie and Doctor Will, recognizing that investigations in unknown fields might lead to discoveries that would change the course of particular diseases, invited Doctor Kendall to join the clinic staff. Certainly Doctor Kendall hit the bull's eye twice when he was given a laboratory and the opportunity to work in the Mayo Clinic and Mayo Foundation as the result of the foresight of Doctor Plummer and the Doctors Mayo.

I must add too that over the continuing years in which Doctor Kendall carried on his adrenal studies many were skeptical of much of importance coming out of them, and since it was a very expensive laboratory to maintain, from time to time objections were raised to its continuation. Fortunately Mr. Harry J. Harwick and members of our sciences committee and of the Board of Governors backed Doctor Kendall from year to year until he attained success, but I shudder to think that had it not been for a few men, particularly those whom I mentioned, Kendall's work would have been discontinued because of the expensive character of the research.

Dr. Leonard G. Rowntree:—Doctor Rowntree brought to the Mayo Clinic the spirit of research in the fields of medicine and was instrumental in gathering a group of men together who had visions of the accomplishments by research in medical fields, some of whom needed to be trained in the application of research methods to clinical problems.

Credit also should be given to Dr. Henry Helmholz for stimulation along these lines, particularly in the fields of pediatric disease. His researches on pyelitis in children were outstanding and his contributions in other fields of pediatrics were internationally known and recognized. Both of these men were given laboratories to work in, animals to use, and the fullest support to their ideas of the development of their particular fields of interest.

Doctor Helmholz brought Dr. Samuel Amberg with him. Doctor Amberg had worked in the laboratories at Johns Hopkins with both Doctor Abel and Doctor Rowntree and in addition to being a clinical pediatrician he was an experimentalist in this field as well. He too helped stimulate this phase of medicine and pediatrics in the Mayo Clinic.

I could mention many others, such as Dr. Henry Plummer, Dr. George Eusterman and Dr. W. F. Braasch, who made important contributions in their fields of specialization during the 1920's and later, but time doesn't permit it. I mention these because I think it is an example of how the leaders, Doctor Will and Doctor Charlie, with foresight and vision of developments in medicine, anticipated that these could be accomplished by a proper choice of men for positions and by giving them opportunities to investigate their ideas in the laboratory and then to make proper application to clinical medicine. You can see in the description of the accomplishments of these men, how, without exception, their researches were confined to problems associated with the recognition of disease and therapy, and were of the utmost importance in their practical application.

I think this has been the keynote of the clinical investigation and research in the Mayo Clinic, namely, research along practical lines which would lead to the practical discoveries that would improve the care of the sick.

Developments in the Field of Surgery

Since all of us are surgeons, a brief view of the development of surgery as seen through the eyes of a surgeon who has had a surgical service for thirty-six years and who prior to that was a surgical assistant for four years should prove interesting.

Contrary to the custom in some clinics, the

practice of surgery by the surgeons of the Mayo Clinic was a matter of individual decision. At no time have the heads of any of the surgical sections been told what type of operation to perform in a given case. Moreover, they have had an individual autonomy. When they are appointed to the staff as surgeons, they are given every opportunity to develop in a field of general surgery, with the institution of whatever ideas, programs of investigation, and teaching methods which they consider to be best. Differences of opinions regarding methods and procedures are openly discussed at surgical staff meetings. However, if surgical results have not justified continuation of certain surgical procedures, the surgeon has not been told not to perform the procedures, but he has decided himself that the results were not equal to procedures that other surgeons were using.

This independence permeated the clinic, and again has showed the foresight of the founders, for instead of impeding progress and preventing new ideas originating in the minds of younger, active, ambitious members of the staff, it stimulated them because they knew their program would always be supported provided that it conformed in general with the practice of medicine and surgery in other institutions as well as our own. As a result, you will remember that from time to time different types of surgical procedures and varying results have been reported by different surgeons at the Mayo Clinic.

One example from a field in which I am particularly interested, that is, surgery of the stomach for gastric and duodenal ulcer, will be mentioned. After returning from a study of this problem in the German surgical clinics, I began to employ the Billroth I resection for duodenal ulcer. Within the next two years I had used it in a sufficient number of these cases to be able to evaluate the results over a short period. I was distressed to find that the incidence of recurrence of the ulceration was about 5 or 6 per cent. I abandoned the operation in favor of the Billroth II or Polya operation. However, during the war while I was away, two of our surgeons, with the idea that perhaps a more extensive resection with the employment of the Billroth I procedure might give better results than had been obtained before, performed this operation in a series of these cases, but as time passed, unfortunately their experience was similar to my own in regard to recurrent ulceration. Since that time relatively few Billroth I anastomoses, in comparison to the Billroth II or Polya anastomoses, have been performed for duodenal ulcer at the Mayo Clinic. It is a good operation, however, for gastric ulcer, for certain small scirrhous carcinomas involving the lower portion of the stomach, and probably for certain patients with duodenal ulcer if a vagotomy is added.

I should like to mention two or three of my own interests which were developed in part by stimulation by older members of the staff and in part by opportunities given to me to carry out programs of investigation. The first of these was shortly after I obtained my surgical service in 1924 when Doctor Braasch, after hearing Doctor Quinby of Boston report his results from plastic operations in the treatment of hydronephrosis, suggested to me that I do some of these operations. He saw to it that patients were referred to me in consultation on whom the plastic procedures might be carried out. After studying the reports of Quinby, and those previously published by Kuster of Germany, I began to resect the renal pelvis, sometimes with reimplantation of the ureter in the dependent part of the resected pelvis, as these investigators and surgeons had advised. The results were good.

In my trip to the foreign surgical clinics in 1927 I saw Hans Wilbolz of Berne, Switzerland, perform two of these operations. In discussing the problems associated with these procedures, he told me that he had done a great many of them on patients with infected hydronephrosis and some patients with bilateral hydronephrosis. His results had been satisfying, and in many instances very good. When I returned home, it happened that I saw two patients with large bilateral hydronephrosis with infection on whom I successfully operated. The results were so good that I was proud to present the patients at a meeting of the Minnesota Medical Association here in the Saint Paul-Minneapolis area. In 1933, Doctor Priestley and I presented a large series of these cases at the meeting of the American Urological Association in Minneapolis.

In 1933, at the meeting of the American Surgical Association to which I had just been elected to membership, I heard Harry Lyle, of Cornell University and St. Luke's Hospital in New York, report successful results from use of the Ombrédanne operation for hypospadias. I looked up Ombrédanne's original article and found that he

had carried out the operation on more than 120 male children, had followed them through puberty and had had a high incidence of success. I then began using this operation, and much to my pleasure, successes greatly increased over those attained with previous methods. The extension of plastic surgery in this field by the late Dr. Hugh Cabot and my colleague, Dr. Ormond Culp, is known to all of you who are interested in this field of surgery.

These results led to an interest in other plastic operations and I began to employ the Torek operation for the treatment of undescended testes after Dr. Herbert Willy Meyer had described the excellent results on follow-up many years after operations performed by Dr. Franz Torek of New York. Torek, you will recall, was a Viennese American, who performed the first successful resection of the esophagus in this country. These operations and the report I made at the German Surgical Congress in 1931 on the postoperative renal function of seventy-six patients with exstrophy of the bladder on whom Doctor Charlie and I had performed ureterosigmoidal anastomosis and cystectomy did more, I think, to start me on my way in urologic surgery than any other particular contribution that I made in this field of surgery.

I mention these not to be boastful but to show how opportunities present themselves for carrying out new procedures in surgery, and how opportunities, if recognized, arise for carrying out studies.

During this time Drs. Albert Snell, Jesse Bollman, Carl Greene and I had been actively interested in lesions of the liver and biliary tract. Doctor Rowntree, recognizing the opportunities available for developing better tests of liver function, and Doctor Mann, by his physiologic studies after hepatectomy in experimental animals, stimulated us to apply in medicine and surgery the results of some of the studies that they and we had carried out. Because of several of these studies I began to prepare jaundiced patients for operation by the intravenous administration of glucose to support the liver, and of a weak solution of calcium chloride to reduce the coagulation time of the blood. The reduced coagulation time, in turn, would reduce the incidence of fatal postoperative hemorrhage. These projects together with the opportunity of working with Doctor Judd, who was particularly interested in lesions of the biliary tract, and the early opportunity of dealing with many complicated cases of biliary tract disease, even strictures of the common bile duct, aroused my interest in this particular field of surgery.

Here again, I think you will recognize the importance of the influence of older men interested in the development of younger men and in giving them opportunities to carry out ideas which the older men may have generated, or suggested. Such influence extends far beyond the year, or the particular few years, of the study.

Doctor Will and Doctor Balfour who were particularly interested in gastric surgery gave me every opportunity to work in this field so that I became interested in cancer of the stomach in addition to peptic ulcer. My interests have continued through the years and I contemplate making comparative studies of these conditions in the Orient after my retirement.

Before World War II one wondered what further developments could possibly occur in the field of general surgery. However, as always, further developments will occur. One only needs to mention the development of the extracorporeal heart-lung apparatus for open-heart surgery, the use of autogenous and then synthetic grafts for vascular replacements and the remarkable developments in the field of cardiac surgery by different surgeons throughout our country, to indicate the continuing advantages of combined clinical and experimental forces in solving problems relating to disease.

No cavity of the human body is now hidden to study and exploration in the correction of deformities or disease. Undoubtedly techniques used to correct lesions will improve in all areas of the body and probably better methods of treatment will decrease the risk of surgical procedures even further. It might be said that further developments in these areas seem unlikely. But that was what we thought about the development of surgery in the 1920's and again in the 1930's, and in the 1940's. Once again in thinking over the almost forty years that I have been in surgery I would say that the greatest development in the fields of surgery has occurred in the last fifteen years.

I want to tell you how pleased I am to have been invited to be your guest this evening and to have an opportunity to reminisce of the life and career of a surgeon who has practiced in Minnesota for forty years.

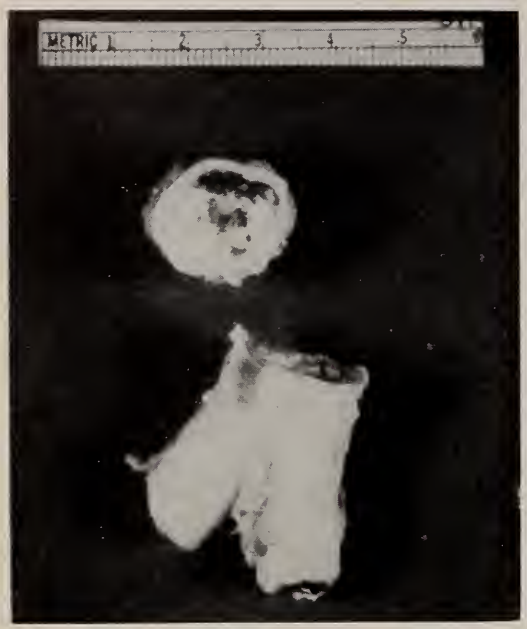

Fig. 1. Specimen of resected aorta and common iliac arteries showing the obliterating tumor thrombus.

Tumor Thrombosis

Of the Abdominal Aorta and Iliac Arteries

Report of a Case

DAVITT A. FELDER, M.D.
Saint Paul, Minnesota

TOTAL OCCLUSION of the abdominal aorta and common iliac arteries by a tumor thrombus is apparently a rare enough entity to warrant its being reported. Several reports of tumor emboli and thrombi with obturating occlusion of the arteries have been documented in the literature.

Thompson and Evans,[1] in their paper on paradoxical embolism in 1930, include one case of a tumor embolism involving the middle cerebral and coronary arteries as a direct metastasis from a teratoma testes. Groth, in 1940,[2] reported a successful embolectomy of a tumor embolism to the left common femoral artery from massive pulmonary metastases two years after amputation of the right lower extremity for the primary osteogenic sarcoma of the femur.

A thrombus containing tumor cells found in an atheromatous ulcer was reported by Branwood and Glazebrook in 1946,[3] in a patient with a sarcoma of the diaphragm with multiple pulmonary metastases.

An abdominal aortic and renal arterial occlusion by a massive embolus in a ten-year-old girl apparently from a myxoma of the left ventricle was reported in 1947 by Young and Hunter.[4]

Till and Fairburn in 1948[5] described a femoral arterial thrombus containing tumor cells from an oat-cell carcinoma of the lung with demonstrable involvement of the pulmonary veins by tumor.

An unsuccessful axillary artery tumor embolectomy was reported by Loosemoore and Whittick in 1951.[6] In their patient, a sixty-four-year-old woman, the embolus presumably came from the lungs containing multiple secondary neoplastic lesions three years after an amputation of the lower extremity for a synovioma of the knee. At necropsy this patient was found to have a large propagation of the tumor along a major pulmonary vein with an embolus from this occluding the vein secondarily. There were also multiple metastases found in the cerebrum, cerebellum, lumbar vertebrae, and thyroid gland but no other gross intravascular tumor masses.

A case of gross arterial embolism from a myxosarcoma of the lung with pulmonary vein invasion was reported by Miller and Jackson in 1954.[7] In this patient, tumor emboli were found in the left atrium, right meningeal, and splenic arteries with invasion of the heart, brain, and spleen, respectively, by tumor tissue presumably from the emboli.

Cera, Karlinsky, and Rodin in 1957[8] reported a case of a squamous cell carcinoma of the lung that had metastasized to the heart vessels and myocardium but had also embolized to and obstructed a coronary artery causing the patient's demise.

The following is the report and discussion of an instance of tumor thrombosis of the abdominal aorta and common iliac arteries and later of the external iliac and common femoral arteries.

Report of Case

This is the case history of a fifty-eight-year-old, white aviation mechanic who was seen in January 1958 for ischemia of the lower extremities. He had a recent past history of increasing soreness of the muscles of the legs and thighs on walking of approximately five months' duration and anorexia of two months' duration.

The patient appeared chronically and acutely ill. He had obviously lost weight and was bedridden with constant pain in his left foot and leg which he held down over the side of the bed for partial relief. The blood pressure and other vital signs were all normal. There was swelling and rubor on dependency in the left foot with early trophic changes in the skin.

Both femoral arterial pulses were barely palpable and no definite arterial pulse could be made out distally in the lower extremities. A tentative diagnosis of occlusion of the aorta secondary to arteriosclerosis was made.

On February 1, 1958 an abdominal aortogram was made which revealed a complete occlusion of the aorta a little below the renal arteries. There appeared to be some delayed filling of both common femoral arteries.

On February 6, 1958 a completely thrombosed aorta and common iliac arteries were resected (Fig. 1) and replaced by a braided nylon arterial prosthesis. The recovery from this procedure was essentially uneventful. All pulses returned in normal amplitude in the right lower extremity and in the left femoral and popliteal arteries. The pain in the left foot disappeared and both feet became warm and dry. Within two weeks the patient could walk as far as he wanted without discomfort. However, he did not regain his strength in normal fashion and his anorexia persisted. He was given treatments with a cortisone derivative and gained 9 pounds in weight but still remained 20 pounds underweight.

On May 5, 1958, three months postoperatively, the patient returned with the complaint of some back pain and pain in the left foot on walking one block. The examination revealed a normal external iliac pulse but none below on the left side. On the right side the pulses were normal. Both feet were warm and dry as before. A diagnosis of occlusion of the left common femoral and distal external iliac artery was made. On May 14, 1958 a left iliofemoral arteriogram corroborated this diagnosis.

On May 28, 1958 a thromboendarterectomy of the left distal external iliac and common femoral arteries was performed. The preoperative pulses returned to the left lower extremity and the patient again could walk without difficulty. Except for a collection of serum in the operative site the recovery was uneventful. His anorexia and weakness continued.

The report of the microscopic study of the aorto-iliac specimen revealed the presence of what appeared to be tumor cells in the occluding thrombus. A review of these tissues was made including a more intensive study of the second endarterectomy specimen. This revealed the presence of undifferentiated tumor cells in both specimens (Figs. 2 and 3). The origin of these could not be identified.

On August 18, 1958 the patient returned with the complaint of pain in his left groin and medial thigh, and weakness of the left thigh muscles. Examination at this time revealed no change in the vascular status, tender-

Fig. 2. Thrombus (*in lower third of the illustration*) and tumor cells (*above*) in abdominal aorta. The thickened intimal vessel wall is seen in the bottom of the photograph.

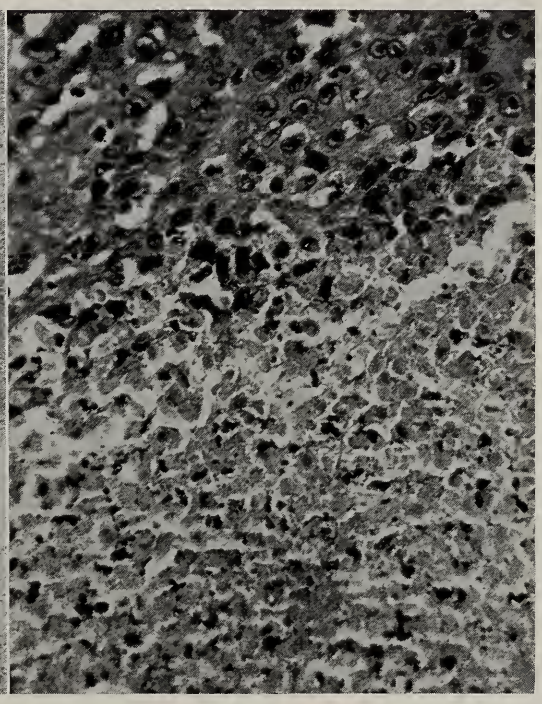

Fig. 3. High power of tumor (*upper half of photo*) and thrombus (*lower half of photo*) in resected abdominal aorta.

ness over the left groin and pubis, and a weakness of the adductor muscle group but no paralysis.

A complete urological examination including an intravenous pyelogram was negative. An x-ray of the pelvis revealed an osteoclastic lesion of the anterior pubic

Fig. 4. Roentgenogram of pelvis showing osteoclastic lesions of the left pubic ramus, femoral head and ilium.

ramus on the left side and suggestions of small lesions in the ilium, neck, and greater trochanter of the left femur (Fig. 4). The spine and chest x-ray examination were essentially negative. On August 21, 1958 an osteotomy of the pubic ramus was made which revealed a tumor of the bone just breaking through the cortex. This was biopsied. Exploration of this area revealed no evidence of vascular or nerve involvement.

Microscopic study of the marrow smears and of the metastatic tumor proper revealed what was thought to be a sarcoma possibly of osteogenic origin (Fig. 5).

The patient was given a total of 1850 roentgens of radiation therapy to the left inguinal region in treatment of this osteolytic lesion in the bone. This was divided into sixteen daily doses. On completion of this therapy the pain and the weakness in the left adductor muscle group were much less and the patient could get up and about with the use of a cane. Approximately one month after this x-ray therapy, further x-ray examination revealed that the tumor process had extended well into the acetabular area and into the ilium. There was also some evidence that the body of L-4 vertebra was becoming demineralized.

Repeated chest x-rays and electrocardiographic studies over the previous few months revealed no abnormalities.

On March 31, 1959 the patient was again admitted to the hospital. At this time, he was in much pain in both groins and thighs and showed a great deal of weight loss and inanition. He was incoherent with only occasional episodes of lucidity and was obviously in a terminal state. No other gross changes of note were made on the physical examination. The patient finally expired quietly on April 17, 1959.

Postmortem examination revealed the aorta above and below the arterial prosthesis to be free of tumor growth both within and outside the lumen. The arterial prosthesis was patent, intact, and no evidence of tumor cells was made out. The left external iliac and common femoral arteries were also patent and free from any evidence of tumor. The lesions of the pubis, femur, and ilium were essentially unchanged with obvious tumor involvement of the bone but with no significant local extra-osseous extension. There were numerous small areas of secondary malignancy throughout the pulmonary parenchyma histologically similar to those found in the pubis and in the resected abdominal aorta. The remaining portion of a complete autopsy, including the central nervous system, revealed no evidence of tumor cells. The heart was normal in all respects with no evidence of a permanent or temporary right to left shunt.

Fig. 5. Microscopic view of biopsy of osteoclastic lesion of the left pubic ramus.

Discussion

Certainly blood-borne metastases whether they arise from single cells or large groups of cells must enter a vein from the primary tumor and travel to their secondary location as emboli. However, it is not usual that such emboli are clinically identified unless they occlude a large enough blood vessel to produce acute symptoms. As has been pointed out above, several of the latter type situations are reported in the literature and some with subsequent successful embolectomy.[1,2,4,6-8] But the case re-

ported here does not fit into this category. It does seem to fit with those cases reported in the literature where large numbers of tumor cells have been found with arterial thrombi both occlusive[5] and non-occlusive,[3] and therefore seems more appropriately described as an instance of tumor thrombosis.

It has been suggested by the studies of Fisher and Baird[9] that patients with neoplasms have a tendency to arterial thrombosis even without tumor cells being present in the occluded vessels and that the presence of tumor cells may enhance thrombus formations. In our case, the question arises whether the tumor cells were present first in the artery and produced secondary thrombosis or whether a thrombus was present which simply trapped tumor cells. Since the vessels in our patient were sclerotic it is likely that the thrombus formed trapping the tumor cells in first the aorto-iliac and later the iliofemoral areas.

Except in the case of Branwood and Glazebrook[3] where an intimal plaque involvement was seen, there was no instance found in the literature in which the neoplasm had invaded the wall of the blood vessel. There was no such involvement in our patient either (Fig. 2). This may be due to the fact that too little time had elapsed in any of the patients for this to take place.

Except for the original diagnosis of undifferentiated sarcoma in the aortic thrombus which may have originated in the pubic ramus, no further light is cast on the origin of this tumor. Original x-ray examination, made incidental to the aortography and arteriography, reveals no apparent changes in the bone of either the pelvis or the lumbosacral spine and femur. This is no proof that the tumor tissue was not primarily present at these sites, however.

In several of the cases reported in the literature[2,3,5-8] the pulmonary lesions were large and grossly visible on x-ray examination and at postmortem, the pulmonary veins were obviously involved. Whereas in our case it was at no time apparent on chest x-rays and at postmortem, the scattered small secondaries were only a few millimeters in diameter and showed no obvious vein involvement.

It is likely that the sarcoma cells metastasized from the lung into the arterial blood stream and were caught first in the thrombosis of an atherosclerotic aorta and common iliac arteries and later in an atherosclerotic external iliac and left common femoral arterial segment. With an intact heart and great vessels no other reasonable or even remote possibility suggests itself to the author as an explanation in this case.

The pain in the upper thigh is difficult to explain on the basis of the left pubic lesion alone. This is especially true in view of the fact that the femoral and obturator nerves were at no time involved with the tumor process. It is further difficult to explain when one finds that at autopsy there was no evidence of impingement on or involvement of the central nervous system with tumor. The exact mechanism of this pain remains unclear.

It can be postulated in view of the findings in this case that the tumor emboli were small enough to pass through the ordinary capillary beds since there were no other peripheral manifestations of tumor metastases; and that only where an extremely narrow lumen existed in the pathway and/or actual thrombosis had taken place, were the cells agglomerated. A final conclusion of the case then must still be that the primary tumor was that of osteogenic growth in the left superior pubic ramus which metastasized with multiple secondary foci of low-growth activity throughout the pulmonary parenchyma. These pulmonary foci, in turn, were the source of the secondary tumor thromboses found in the aorto-iliac and the left iliofemoral arterial regions.

LAW—MEDICINE—RESEARCH

The future of a law-medicine relationship within a university environment is encompassed in the word *research*. This word, as it pertains to medicine, is well understood by medical practitioners. In law, research is an almost unknown endeavor. Medicine traditionally has advanced through the scientific laboratory. Law advances through the public courtroom and the attitudes of the market-place. The strength of medicine is measured by the quantity and quality of scientific research. The strength of law is marked by its acceptance among common men living their daily lives. Within the past decade, legal scholars in the university environment have just begun earnest research programs dedicated to the improvement of law and justice. A few voices in the past half-century have called upon the legal profession to undergird legal research with an eye to the improvement of justice. Never-theless, it is a fair statement that even today most lawyers conceive the law's progress to be the result only of court decisions and legislative enactments, not university research. Medicine practices at its finest within great university environments. Law practices at its finest within courtrooms, hearing offices and legislative halls.

The first blessing which medicine bestows on law is the acknowledgment of the wisdom in scholarly research. One practical result of this acknowledgment was described in the previous editorial on "Homicide" published in the February issue of this journal. More scholarly research in the law-medicine area is inevitable. Not only the example of medicine but the complexities of modern urban, industrial society demand of law, thoughtful research and experimentation in the laboratory—albeit the laboratory of a human community. A university oriented law-medicine center is the obvious agency to provide such a common research program.

What areas of human life will require major law-medicine research? One foremost in the picture today involves the mentally disabled and the law. Already in several law schools, joint efforts in this area of study are underway. The University of Pennsylvania, Temple University, Yale University, Western Reserve University, are among these institutions already concerned. But more important, the practicing lawyers of America through the American Bar Association Foundation have assigned this topic as one for immediate research activity. Through a special committee composed of Judge Stephan C. Chandler, U. S. District Court of Oklahoma, Judge David L. Bazelon, U. S. Court of Appeals of the District of Columbia, Frank P. Fosgate Esq., of Wisconsin, Judge J. Howard Ziemann, Superior Court of California and this writer, a survey of medico-legal procedures in the commitment and discharge of the mentally ill will soon begin. A grant in excess of $80,000 from the National Institute of Mental Health will underwrite this law-medicine research project.

Further research possibilities in the forensic psychiatry area would include a study of the criminal insanity rule which is now in a period of great intellectual and practical fermentation. The *McNaghten rules* of 1843 have been seriously altered by the *Durham rule* of 1954. Under the former rule, an accused person is criminally liable if during the act he knew right from wrong and if he knew the act he was doing; under the latter rule he is liable if the act he did was not the product of a mental disease or defect. What are the effects of each standard of insanity on the local communities? Are criminals escaping punishment? Is the accused a criminal or a patient? How should this be determined? By whom? How and when should an insane accused person be released to return to society? These questions require more than the traditional emotional answers given by juries of common citizens. Intellectual solutions are in order and desparately needed.

Even further in the future, law-medicine research must aid in the preservation of social peace, individual liberty and personal equality. Today it is obvious that mental behavior of the individual and the group is crucial to conserve our society under law. Professors Brown, Bonner

and Weir in *The Next Hundred Years,* 153-4 (1957) have stated:

"When we take the very long view of man's world in the next century we see that the main problems are less those of technology than they are those of men getting along with other men, communicating with other men, and organizing themselves in such a way that their genius and imagination can be vigorously applied to the problems that confront them. Our major problems involve the enriching, enlarging, improving and mobilizing of our intellectual forces.

* * *

"We have seen that, in principle, man can, if he wills it, create a world where people can lead lives of abundance and creativity within the framework of a free society. It is apparent that there will be many difficulties; there will be many dangers. But it seems reasonably clear what man must do in order that the path may be negotiated. It remains to be seen whether he will recognize these problems in time and proceed to create a still higher level of integration, or whether he will permit his civilization at its present stage of development to disintegrate, perhaps never to reappear. The future of industrial society revolves around the question of whether man can learn to live with man."

The tool man uses to get along with other men is law. The ideas man uses to guide this tool emerge from his mind which medicine can reveal, analyze and explain. A law-medicine center should be dedicated to this joint research so vital to the future of man.

A more immediate research project for law-medicine involves the use of the medical expert witness in personal injury jury trials and administrative hearings for workmen's compensation, social security or veterans benefits. Each of these facets of common law justice requires truthful facts and opinions upon which to base the law and to produce a just and fair decision. Is the adversary proceedings the pathway to truthful medical facts and opinions? Should the doctor be the court's witness, not a party's witness? Can administrative referees render valid awards on written medical reports alone?

The impartial medical panel for jury cases has been invoked in several communities. In New York City, such a procedure includes court testimony. In Cleveland, the plan does not go as far as the court trial but is limited to pre-trial activity only. Which is better for the administration of justice and why? Answers to these questions are the responsibility of law-medicine research in a scholarly university environment outside the arena of legal conflict where partisan, adversary opinions predominate.

Many persons commend the law-medicine courses and institutes sponsored throughout our nation today. None can deny their value in bringing better understanding between lawyers and doctors. The true mark of success in the law-medicine relationhip will not emerge, however, until scholarly university research is dedicated to the advancement of law-medicine justice.

Oliver Schroeder, Jr.

FOOD AND RESTAURANT SANITATION CONTROL

Most physicians are aware that much of the illness popularly referred to as summer flu, stomach flu or intestinal flu, is, in fact, food infection or food intoxication, caused by faulty food handling practices either at home or in a public establishment. Families have learned to accept an occasional gastrointestinal upset as something that is "going around" and that will pass in a day or two. For this reason, relatively few of such cases are treated by physicians or come to the attention of health officials. It is usually only when a large number of people are afflicted at once, as a result of eating a meal together, that any publicity is given to the episode. This is the reason that church or community dinners are so often incriminated while, as a matter of fact, many more cases may occur independently from eating at a public restaurant.

Although the occasional case of typhoid fever that occurs in Minnesota is most likely to have been transmitted by careless handling of food, now that water and milk supplies are under improved sanitary control, other salmonella infections and staphylococcus food poisoning are the food-borne illnesses that are of greatest concern to public health officials because of their frequent occurrence. Respiratory infections, also, may be transmitted through food service when the food handling personnel are unaware of, or indifferent to, the hygienic principles involved.

People, generally, regard an inspector as a necessary evil inherent in any control program. They expect him to make someone do something because it is "the law" and as a penalty for wrongdoing. Little is gained by punishing a restaurant operator for a violation of good practice unless he is informed of the public health reason behind the rules. He is likely to know that the inspector probably will not return for some time, and unless he is convinced that it is for his own economic good

to comply all of the time he may soon forget to do so. No restaurant operator wants to make his customers sick, but unless he has some knowledge of how his faulty food handling practices have been or can be responsible for illness he will continue to operate as he always has. It is true, of course, that some operators refuse to be convinced, but this, too, is probably due to the lack of reporting of cases of illness.

Because of a recognition of these factors, the state food service control program in Minnesota is based more on educational measures than on police or enforcement methods. Even with an inadequate staff, capable of making less than one-third of the inspections that should be made, this approach has been effective in a small way. Most food service personnel and operators are interested in learning the elements of disease transmission and take pride in the knowledge they gain, but inability to make return inspections with the desirable frequency (at least two inspections a year) reduces the effectiveness of the program. Efforts to obtain the necessary legislation to expand the program have been unsuccessful but will be continued.

Minnesota has many of the finest eating places to be found anywhere. The operators of these, in general, endeavor to adhere to the best sanitation practices and favor an effective program of control to maintain high standards for all establishments. A person who has become ill of food poisoning often has at least a vague idea of where he acquired his illness and, while he does not go to the trouble to report to anyone, he is likely to avoid that establishment and possibly any other in the same community or even the same section of the state. In the case of an out-of-state tourist this aversion may be great enough to make him feel he is not safe, because of an inadequate control program, to eat a meal in a public place anywhere in the state. Thus, the lack of an effective program reflects not only on the establishment involved but also on the industry generally.

THE LUPUS ERYTHEMATOSUS AGGLUTINATION TEST

Since the original descriptions of the lupus erythematosus cell, an impressive array of techniques for demonstrating the presence of lupus erythematosus cell factor has appeared. The large number of methods available suggests that none of them are completely satisfactory and all of them have serious limitations.

There is ample experimental evidence to show that the only contribution which the patient must make in these tests is the lupus erythematosus cell factor. The nucleoprotein substrate upon which the lupus erythematosus cell factor exerts its activity may be provided by the patient, by another human or it may be obtained from animal or bacterial sources. The indicator system used to identify combination of the lupus erythematosus cell factor and nucleoprotein may be a viable leukocyte, hemagglutination, immunofluorescence or complement fixation.

Our current study describes the results of the reaction between polystyrene particles which have been coated with calf thymus nucleoprotein and the serum of patients with systemic lupus erythematosus. The coated particles have been shown to remove the lupus erythematosus cell promoting activity from serum and the test can be inhibited by preliminary treatment of the coated particles with desoxyribonuclease. Particle agglutination in dilutions greater than 1:8 are considered positive. One of the outstanding advantages of this test system is its ready adaptability to running large numbers of tests simultaneously.

Sera from 1,000 patients, thought not to have systemic lupus erythematosus, were found not to agglutinate the coated polystyrene particles. Approximately 3 per cent of these sera, however, agglutinated uncoated polystyrene particles and for that reason such "non-specific" reactions must be identified by including a control consisting of the serum under examination and uncoated particles.

Sera from seventy patients meeting the clinical criteria and, in some instances, the pathologic criteria of systemic lupus erythematosus were examined by both the agglutination test and by the classical L-E cell test. Thirty-six of seventy had both tests positive. Twelve of seventy had a positive L-E cell test and a negative agglutination test. Twenty of seventy had a positive agglutination test and a negative L-E cell test.

It is concluded that the L-E agglutination test using nucleoprotein coated polystyrene particles is of value in the detection of L-E cell factor and is readily adaptable for the examination of relatively large numbers of sera simultaneously.

VOCATIONAL REHABILITATION

In the first of this series of articles on rehabilitation in Minnesota, Dr. Frank Krusen not only presented the modern concept of rehabilitation but also told how the State Division of Vocational Rehabilitation has more than doubled the number of disabled persons rehabilitated in the past four years —from 582 in 1955 to 1173 in 1959. This article will attempt to present the reasons for this growth of the rehabilitation movement, an overview of the operation of the Division of Vocational Rehabilitation, and how members of the medical profession have vigorously and effectively contributed to the development of a good rehabilitation program in Minnesota.

In the history of sociological movements, vocational rehabilitation is a comparative newcomer as the first federal legislation providing for the retraining of disabled workers was passed in 1920. Minnesota was among the first states to adopt enabling legislation that established a state rehabilitation agency that same year. These pioneer programs in vocational rehabilitation developed the state-federal partnerships that still exist today, but until 1943 vocational counseling and limited retraining programs were the only services provided.

Legislation passed in 1943 set the pattern for services of vocational rehabilitation as administered today. Mental illness and mental retardation were recognized as vocational handicaps and new services were added to the basic program of vocational counseling and training. These included medical services to reduce the functional limitation imposed by a disability, prosthetic devices, maintenance during training period, tools and equipment needed for employment and increased effort in job placement.

From 1943 to 1954, there was a slow and steady development of vocational rehabilitation in Minnesota, but it was the passage of Public Law 565, *"The Rehabilitation Act of 1954,"* that marked the opening of the modern era in rehabilitation. By substantial increases in the budget for rehabilitation, it has made possible expansion of staff and offices to bring rehabilitation closer to all areas of the state and reduce the geographical area and the number of clients each counselor must serve; many more severely disabled persons can be provided the physical restoration and evaluative services, and staff time and case service funds are available to provide prevocational diagnoses and "job-readiness" psychological adjustment for the many clients whose psychological and emotional problems are often greater than their physical impairment.

By making available federal grants for extension and improvement of rehabilitation facilities, Public Law 565 has added many new resources for evaluation and training of the severely disabled in Minnesota and during the past four years there has been a very gratifying increase in the number of mentally ill, mentally retarded, and other types of severely disabled persons among the persons rehabilitated.

This progress in vocational rehabilitation has been concomitant with progress in medical science. New drugs and psychotherapeutic techniques have tremendously increased the number of mentally ill persons who are able to leave a hospital and embark upon a vocational rehabilitation program to prepare them for a return to their homes and productive employment. Similar advances in treatment of neurological diseases, tuberculosis, poliomyelitis, diseases of the heart and cardiovascular system and orthopedic disabilities have all given new life and new hope to persons who might have been considered hopelessly disabled a few years ago.

All of this has had a dramatic impact upon vocational rehabilitation. It has focused public attention upon the sociological and economic disaster caused by disability, which in turn, has resulted in legislation like Public Law 565. It has created a new concept of the type of person who needs and can benefit from rehabilitation services and it has strengthened the relationship between the medical profession and vocational rehabilitation. For it is by working together, sharing their professional skills and knowledge, that the doctor and the rehabilitation counselor can be of greatest service to their mutual patient/client.

Evidence of this mutual cooperation is shown by vocational rehabilitation caseload records which show a steady increase in the number of rehabilitants who were referred to the division from the medical profession. In the past few years, medical resources have been first in the number of clients referred to the division, accounting for nearly a third of the persons rehabilitated each year.

The importance of early referral to a vocational rehabilitation resource has been demonstrated time and time again in Minnesota's major rehabilitation centers. When a severely disabled person is contacted by a rehabilitation counselor soon after the

onset of disability (often while the patient is still hospitalized), there is a much better prognosis for successful rehabilitation than if the patient is rehabilitated physically and sent back to his home and months, or even years, go by before any contact is made with a vocational rehabilitation agency. And the same holds true in cases where the private practitioner had made the earliest possible referral of the patients who may be aided by vocational rehabilitation.

Often the goal of a useful, productive life represented by a definite plan of vocational rehabilitation gives the despondent and indifferent patient the necessary motivation to follow through with a lengthy, tiring program of treatment and therapy planned by his physician.

By strengthening the inter-action and coordination of services between physical and vocational rehabilitation, between the doctor and the counselor, a much more complete and comprehensive rehabilitation service will be provided for the disabled. The increasing number of aged and disabled persons in our population make it imperative that such services be expanded. For unless they are restored to social and economic self-sufficiency, care of the aged and disabled will become a tremendous drain upon the economy of our communities, state and nation.

August W. Gehrke
State Department of Education

EFFICIENCY—GOVERNMENT STYLE: A FABLE (???)

A small private hospital of 100 beds ran efficiently with an administrative staff of one administrator, one business manager, and five secretaries. The house staff consisted of three residents and six interns who were paid by the hospital. They were taught by the staff doctors who were in private practice and received no pay. This hospital was filled with patients who received excellent care. There was no waiting list, and the people in the community were happy and healthy.

Then this fine hospital was taken over by the state. First came the administrator and his two assistants and each had two secretaries. Since there was not enough office space, five patient rooms were converted into offices. Next arrived the business manager with his two assistants and their six secretaries and with them went ten more hospital beds. The efficiency expert arrived with an assistant and three secretaries, and they used up five more rooms. The professional staff expanded to twelve full time chiefs, each with a full time assistant and each one with at least one secretary. The house staff went from nine to fifty-five. Each department needed a research laboratory, so more beds were appropriated. When the reorganization was over, the hospital, which had been operating on a budget of $300,000 a year —paid by the patients—was costing three and a half million a year — paid by the taxpayers. This, of course, did not include the $300,000 received in federal grants for research of questionable necessity and merit—also paid by the taxpayer.

At this time, it was discovered that the need for office space had left only one bed for patients. Immediately each department claimed the single bed. As a result, the only patient in the place alternated between complete neglect, examination, and treatment by the whole staff. The strain of fifty physical examinations a day, supplemented by millions of laboratory tests, conflicting, cancelled, and reordered orders, along with infusions, transfusions, enemas, lavage, gavage, etc., brought on his early demise. Autopsy revealed death was caused by exhaustion, acute therapeutic anemia, and a perforated stress ulcer.

With the death of the single patient, the last remaining bed was converted into a conference room. Here the staff met and, after months of deliberation, came up with a brilliant solution—they sent a request to the state legislature for ten million dollars to build a new 100-bed hospital.

Saint Paul 2, Minnesota

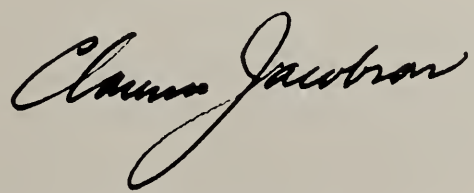
President's Letter

WHO WILL BE OUR SUCCESSORS?

The present status and the future prospects of enrollment in our medical schools has been called to our attention by government agencies, economists, and our own national organizations. The quality of the present applicant has given our medical schools concern.

In 1950, 5.1 per cent of college graduates applied for admission. In 1958, the number dropped to 4.1 per cent. "A" grade applicants decreased; a decline in quantitative aptitudes and scientific skills as measured by aptitude tests. Freshman withdrawal during the freshman year increased from 5.5 per cent in 1954 and 1955 to 7.8 per cent in 1957 and 1958. This made fewer students available for the second year.

Aside from the quality student, faculty vacancies in 1957 and 1958 were twice that reported for the period of 1956 and 1957. Twenty medical schools reported an average need of fifty additional faculty members.



In 1959, there were eighty-six medical schools in the United States including four two-year schools. These would admit 8,250 students in 1960. Expansion and rehabilitation would permit these to admit 9,400 in 1966. It is clearly apparent there is a shortage of physicians and teaching facilities in our country in relation to the present rate of population increase. Assuming that by 1975 there will be 235,000,000 people, 310,000 physicians would be needed to maintain the desired 132 physicians to 100,000 population. At the present time, there are approximately 230,000 physicians in practice and research.

Our situation in Minnesota appears to be fair with regard to selectivity. In 1954 to 1958, there were on the average 316 applicants out of which 130 students were selected yearly. In 1959, there were 319 applicants out of which 137 were selected; 1960 saw 140 selected from 337 applicants.

Among the factors which account for the present decline of qualified applicants are the long years of formal training as compared to other professions. Counting premedical training, up to nine years are required to prepare for general practice and from twelve to fifteen years for the special fields. The increase in the number of married students has become significant. In 1956, 55 per cent, and in 1958, 68 per cent of students in medical school were married. Twelve per cent had two or more children in 1956; in 1958, the number had increased to 24 per cent. These factors loom as economic barriers to many. At best can we postulate that the medical student of today is superior in dedication, stability, and motivation by virtue of meeting these formidable obstacles and overcoming them? Surely, he has additional preparation for better understanding and maturity to fulfill his duty to his patients.

Leaders in medical education are re-evaluating the curriculi and in some schools have succeeded in shortening the period of preparation with the view of maintaining and possibly improving standards.

We, as physicians, can renew our efforts in our local communities to interview and encourage high school students who indicate interest in medicine. Several county societies have organized groups or "clubs" with these young aspirants with success. Our high standards as a profession will be jeopardized if we fail to realize our precarious situation. We must be aroused as individual physicians to act before we are compelled to submit to bureaucratic control.

President, *Minnesota State Medical Association*

Medical Economics

Edited by the
Committee on Medical Economics,
Minnesota State Medical Association
George Earl, M.D., Chairman

THE FACTS OF LIFE IN THE FUTURE OF AMERICAN MEDICINE

DR. JOHN B. RECKLESS
Duke Universiy Medical Center
Durham, North Carolina

I believe that a comparison can be made between the practice of medicine here and the practice of medicine in Great Britain as it was before the National Health Service. There are, of course, differences, but basically it was a system of private enterprise giving, or trying to give, comprehensive medical care.

So this then is to be my theme: To take a look at some of the changes arising as a consequence of the British National Health Service; a look at the attitudes of the patients; an attempt to review the beneficial changes, for there have been many, many good things which have arisen as a result of the British National Health Service. But there are other things that were not expected, that are not so popular and which have led to difficulties for the British physician.

Let me first begin by telling you just what the National Health Service covers. I am sure every one of you knows it covers a complete physician care, at the family doctor and hospital level. Hospitalization covers both in-patient care and outpatient diagnostic procedures. It also covers a lot of other things—dental care, extractions and provisions for dentures. It covers sight testing and provision for spectacles. It covers appliances, even wigs and toupees, if considered necessary for therapeutic reasons.

There are even more things to come. The service provides complete ambulance service. Any sick person requiring an ambulance telephones and is taken to the hospital. It covers the home nursing care of patients who are convalescing or who don't require hospitalization. It will even provide domestic help if a mother is ill and unable to take care of her family. It provides maternity and death benefits. This is literally a cradle to the grave, or, dare I say it, provides care from the womb to the tomb operation.

National Health Service Economics Explained

I would like now to consider the economics of the service. I am sure many people have heard that many doctors in England are dissatisfied with the pay scale. We are also, I think, very dissatisfied with the per capita fee system. By this system, a doctor is paid approximately $3.00 per patient for 24-hour coverage for 365 days of the year. A doctor is permitted to have a maximum of 3,500 patients. Technically, he may have private practice as well, but, as you will see, private practice has diminished to approximately five per cent. There are very few doctors today who live solely by private practice. Thus, if a doctor has a maximum number of patients, which few have, he is hard put to care for 3,500 patients.

A quick translation into American terms, which is made by economists in England and America, shows that if a man carries 3,500 patients, then he will have a buying power equivalent to $8,110 before deduction of taxes and practice costs. That doesn't sound perhaps too much but this puts such a doctor in an income group which is in the top 1.4 per cent of income levels in the country.

The average number of patients is 2,300 and gives a standard of living equivalent to $6,000. If a physician earns this sum of money, then he is in the top 2.5 per cent of the national income group.

The patient pays the equivalent of $1.32 per week, with the employer paying $1.08 and $.90 for men and women, respectively. This averages out 3.6 per cent of the average annual wage, or $140 per year from direct contributions and indirect taxation. All these figures were calculated very carefully and were published in 1958. Over here, on a similar scale, the average earner would pay $186 per year.

The National Health Service takes approximately 10 per cent of the budget. This is a fact which the

public did not realize and is a point which I think is important for people over here to understand. This is that a government can levy charges for a service not only directly by taking a contribution from a person's income, but also by direct and indirect taxation.

Now your taxation per head is calculated at 24 per cent. Our direct taxation is 40 per cent, and is a matter of great embarrassment for the politicians. Of course, the service blossomed and is so expensive that few countries could afford to imitate this, however, I have a feeling that many are trying.

National Health Service Has Long History

How did this service come to be? Is this the product of a communist or near-communist government? Not at all! This service had its inception in 1911, which is when the government started its first compulsory health insurance bill. This was called a National Insurance Act. This provided family doctor care for any worker earning less than $775 a year. All workers and employers had to belong to this system. They had a very good reason when it was first formed, for it was to protect the wage earner. You can see that he received the appropriate care at the necessary time and this would be for the ultimate benefit of the worker's family. But what it didn't do was to provide for the wife and dependents. It also did not provide hospital coverage or specialist consultation. But it did offer free medicine.

When this system came in, the profession was a little skeptical about it, but over the course of the years it was accepted and the medical profession itself recommended in 1930 and 1938 that the scheme be broadened to include the family, and to include consultant, ophthalmic, dental and maternity care.

Then came the war, and of course, all plans went on the shelf. In 1942, a gentleman named Beveridge produced a system of comprehensive coverage. We had a coalition government at that time with Winston Churchill as prime minister. It was Winston Churchill's government which said that as soon as the war ended, "We'll give this broad coverage."

The profession then became a little anxious and negotiations began to take place. In 1944, one of the members of the government proposed a full-time salaried hospital service with the doctor working for the local city authority. This, of course, was rejected outright. But both parties, both the conservative and labor parties, when they went to the polls in 1945 had as their platform a comprehensive medical scheme. Both were committed to introducing such a service.

Well, as you know, it was the Labor Party, the left wing, that was elected and they announced quite arbitrarily that whatever the profession felt, they were going to introduce their scheme on July 5, 1948. This was announced in 1946.

Well, there was tremendous hustle and bustle in the profession, everyone running in different directions and taking different viewpoints. A referendum was taken and only 17 per cent of the profession were willing to join such a service. We said to the government, "How can you work such a scheme if you have no doctors? You have only 17 per cent."

Divide and Conquer Technique Used

The man in charge, Aneurin Bevan, said, "I don't care. I'm going ahead."

This is how they started that old government maneuver, "divide and conquer," which I am sure is applicable here as well as in other countries. He said, "If a doctor joins now, we will buy his practice and the good will. Secondly, we will give him seniority in the service. And thirdly, we will give full pension rights after ten years in the service."

The older men who were looking toward retirement felt that as an inducement to join the service. There was leadership; plenty of voices were raised, but there was no unanimous voice. A second referendum was taken and 49 per cent of the profession signified they would take part in this scheme. The government said, "We have 49 per cent, so we are going ahead." This they did, and by 1948 they had sufficient practitioners to initiate the service.

Image of General Practitioner Changes

At this point, I would like to switch to the second part of my presentation. You have heard it said that I am a psychiatrist. When people ask what I am, I tell them I am a physician. If they press me, I say I deal with mental diseases. This reminds me of a story of the school teacher who was asking her pupils what their fathers did. She came to one little boy and said, "What does your father do?"

He said, "My daddy plays the piano in a burlesque house."

She didn't think this was a very good moral background for the boy, so she arranged for a visit to his home. She found he had an address in a very fashionable suburb of the city. It was a beautiful house. When she rang the bell, a maid answered. She said, "I would like to see Johnny's father." The maid showed her into a library, where a distinguished looking man met her. She said, "Good gracious me! You're not a bit like what I had expected. Your son, Johnny, said you played piano in a burlesque house."

He said, "Well, actually, I'm a psychiatrist, but I haven't the heart to tell the boy."

Now I want you to imagine that I am not alone on this platform today. On my left I have Dr. X, who is a general practitioner from the days preceding the National Health Service. On my right I have Dr. Y, who is a general practitioner in the National Health Service. I am going to ask them to tell you their likes and dislikes.

Let me first diverge, however, and say that 85 per cent or thereabouts of our profession is in general practice. The rest are specialists. If a patient wished to have a specialist consultation, he usually went through the recommendation of his general practitioner.

Now let's call on Dr. X. He is a well set up gentleman. He has a good suit, a nice car, not the equivalent Cadillac, or a Chrysler, or Lincoln, but it is a good car and it is paid for. He tells you that one of the things he likes about the practice of medicine before the National Health Service is, first, that he can practice where he pleases. I am sure it is the same here, that a man has a choice of a resort area or a country practice where perhaps there are more difficulties in getting started and when you are established there is less income but life is very pleasant. Or one can go into an industrial community where there are always more patients than doctors—where one can recover the cost of one's education quickly and have a fairly high standard of living even though you don't have time to enjoy what you make.

Now this is very comforting because a man knows that whatever he chooses he can change his location. As a doctor becomes older, he may have a cardiac condition and want to take life easier. Dr. X will tell us he knows he can sell his practice and buy a practice at a seaside resort or in the country. This is very comforting for him.

The other thing he likes is the clinical freedom. He is responsible to his colleagues and his conscience and his patients—nobody else. Since all the specialists are dependent upon him for referrals, he is well considered by the specialists. His opinion is solicited. He is encouraged to put a patient in the hospital and take care of him—with the help of the appropriate specialist. This was a very, very nice arrangement. An interesting patient could be admitted to the hospital and the general practitioner could prescribe appropriate treatment. He could take holidays when he liked and, of course, like all doctors, he enjoys a very comfortable status in the community. He could be a civic leader and be very respected. People would solicit his opinion on many things outside medicine.

The things that Dr. X doesn't like are the cost of drugs and the cost of hospitalization for a patient who doesn't have much money. He didn't like, I think, the fact that he would like to make more visits with certain patients but financial circumstances precluded this. The other difficulty was that our specialists were dependent upon private practice and they had to be located around the large cities and teaching hospitals.

There were problems in neuro-surgery or thoracic surgery, especially from trauma, when it might not be possible to get an appropriate specialist, except by transporting the patient to a bigger center.

How about Dr. Y? He doesn't look quite as happy. He looks harassed. Let's ask him to tell us what he likes and what he doesn't like.

The things he likes are that now there is a comprehensive system providing medical care for all people regardless of social and economic status. This is very comforting. He likes the fact he can visit as he wishes. And he likes the annuity scheme whereby 6 per cent of his income and the equivalent of 8 per cent from the government are put together to provide an annuity when he retires.

One of the things he dislikes is the fact that he no longer owns his own practice. He dislikes the fact that he has difficulty in practicing where he chooses. We have more doctors applying for vacancies than there are vacancies available. A doctor, whenever he reads of a vacancy, may put his name forward, but there may be as many as thirty doctors competing for that one vacancy. If he is in an industrial center and would like to switch to a country practice, it can be difficult. Transfers can be made, but with nowhere near

the same ease as before the inception of the service.

And another thing is that when the doctor is older, the National Health Service Authority, consisting of predominantly non-medical people, and responsible for appointing that doctor, may look at the problem differently and say, "We want a young doctor, one who will be able to practice for a few years to come." This also makes it very difficult for the older man to transfer.

High Taxes Force Use of National Health Service

There is, of course, the question of private practice. The government paid lip service to the fact that private practice could co-exist with the National Health Service. But there is one restriction that has caused a lot of heartburn in the profession. Although everybody belongs to the service, if a person comes to you as a private patient, any drugs that you prescribe for the patient he has to buy himself. You know very well the cost of antibiotics, and in the case of a serious illness this can amount to a tremendous sum of money. Therefore, this has been a very great deterrent against people consulting a physician privately.

High taxation has meant that middle income groups and even upper income groups have had difficulty meeting their taxation and therefore they come to the doctor and say, especially when they wish to educate the children: "Doctor, I have been a patient of yours for a good many years. We have always been good friends, but I am afraid I am going to have to go on the service." You understand the position, of course, and so another patient is lost to private practice.

You heard me say that the average doctor is in the top 2.5 per cent of income bracket and yet you will recall that the physicians in Great Britain agreed to strike. A tremendous percentage, I think 70 per cent, agreed to withdraw from the service.

Now we, as a profession, tend to be conservative and a strike is very distasteful. Yet so strongly did physicians feel about it. Why? Because when the government came into power they gave assurance with a rise in the cost of living there would be an increase in the remuneration. But the cost of the service was so great that the government said, "We can't afford to pay you more." Our claims have been put off and put off by successive governments, who say "A decision taken by a previous government cannot be binding upon us today."

When we agreed to withdraw from the service, the government met the situation in a very skillful manner. They said, "We will give an immediate 10 per cent raise to all interns and residents." Since they earn the equivalent of $90 a month, this wasn't much. And they said, "We will submit the claims of the profession as a whole to a Royal Commission." A Royal Commission takes up to three years to sift the evidence and present its findings.

Immediately, those in the profession who found the strike distasteful said, "Well, the government is doing something. Let's cooperate and wait."

So another three years have gone by, and here we are on the eleventh year. There have been some adjustments, but the adjustments have nowhere near equalled the rise in the cost of living.

Government Medicine Curbs Incentive

Another thing is that such a scheme destroys incentive. No matter how few patients you see, your income is the same. As far as the patient is concerned, no matter how often or little they attend, the charges which they pay are the same. So this has led to a number of abuses.

In 1958, the profession took stock of the service after ten years. They found that a number of good things had happened.

There was a dispersion of specialist services and an upgrading of hospitals. All hospitals were given an adequate number of consultants. The men were very well qualified and every town and every city had its complement of specialists. This means, from a doctor's point of view, he can refer a patient to any hospital and know that patient will get very competent, efficient care.

Another thing is that it is a comprehensive medical service.

Some very unusual things have happened, however, and I am sure the same sort of thing could happen over here.

In the first three years of the service, in a country of forty-eight million people, there were 609 million prescriptions and drugs issued. Seven million sets of dentures were issued. Seven hundred thousand appliances were issued. Of course, the cost just skyrocketed. The government was embarrassed and didn't know what to do. So they had to impose restrictions. They said you must pay a shilling on a prescription. A shilling is approximately 14 cents.

You would pay up to a maximum of $2.80 if you went to a dentist for a tooth extraction.

You would pay $4.20 towards the cost of spectacles.

You would pay $12.00 towards the cost of dentures.

And, of course, the actual deductions from the payroll also increased. So the consumer, the patient, John Q. Public, as he is referred to in another presentation, was paying through direct deduction from his payroll and also by heavy direct and indirect taxation.

To give you an example of the indirect taxation, we had a sales tax as high as 66 per cent on automobiles, and a tax of 50 per cent plus on luxury items, such as all electrical appliances, ice boxes, television sets, furs, jewelry, cameras—a tremendous sales tax. So you see, the patient is paying a tremendous sum of money for the service, and unfortunately, I am sure this is your dilemma, too. The public doesn't view things in a long-term way.

Elective Surgery on "Waiting Line" Basis

In 1956, the cost of bottles for giving away the free medicines was $2,800,000. And the money spent on research in mental health was approximately $200,000.

I am sure you have heard that 500,000 people are waiting for elective surgery, and they are still waiting, tonsillectomies and things of that kind. For that, one has to wait.

Another thing, no new hospitals were built. We had suffered, of course, because a number of hospitals had been destroyed in the blitz during the war. There was an urgent need. The population has expanded. But no new major hospitals were built. And I learned last Saturday through a BBC (British Broadcasting Company) presentation, that not since 1870 has so little money been spent upon the construction of hospitals.

Now, how has this affected the status of the individual physician? I am sure it is a point of great interest to you all. Doctors, of course, have now had a greater number of patients to take care of, or at least a greater number of visits by patients. This means in order to see everyone a doctor has had to treat, I am afraid, the disease rather than the patient.

Now the treatment and diagnosis have been thorough and efficient. But if you have twenty to thirty or even forty patients in the office you don't have time to talk about little Willie's scholarship to the university or grand-dad's corns, or what is going to happen when the patient's teen-age daughter marries Joe Bloak down the street. You have to treat the disease. You do not have time to give the patient the sort of contact that you had before the service. I think now, especially with young people, this is a problem. I spent time in different types of general practice in three locations. I think that the younger people now tend to regard the doctor as a man whose services have been paid for; therefore, if a patient feels he needs to be seen, whether for a headache or for aspirin, or he needs to take time off from work and wants a sick note, he will come to the doctor. He knows the doctor is being paid and he believes he has the right to see the doctor. If the doctor is busy, that's too bad. He says, "Doctor, I come once a year. You think it is not important. Nevertheless, I am not a doctor and I want to consult you."

MD Has the Role of a Government Servant

The physician is regarded more now as a government servant. I think this inevitably is going to have an effect upon the caliber of men entering the profession. I am very proud to belong to the British medical profession. I think you are all aware that our standards are as high as anywhere in the world and the individual caliber of the men is very high. But one thing that has come out is that fewer and fewer physicians are persuading their sons to enter the profession. I think this is very revealing.

Of course, the status of the physician's wife has inevitably been altered because of the fixed income, and with the private practice diminished, a doctor can't afford to have all the help he would like. Therefore, more and more wives are assisting their husband-physicians.

Another thing that has happened, which I am sure is very serious, is that the control of the profession has now moved out of the profession. Before, a man was responsible to the General Medical Council. This was composed of his colleagues nationally elected who would deal with any matters of discipline or ethics.

Now he is responsible to a National Health Tribunal and National Health Executive Council. The GMC is still there, but the things that affect a doctor's livelihood and independence and right to practice are now under direct government control. A doctor can be reprimanded or suspended

from the service for a deficiency which is not medical. If a doctor consistently misplaces his National Health Service records he will be reprimanded. If it continues, he can be suspended from the National Health Service. And you can imagine what it will entail.

Dispensing of Drugs Limited

All prescriptions are checked at routine intervals, and if it is found that one doctor is consistently prescribing more than his colleagues in that area, he will be called to account to the appropriate National Health Service body for this so-called over-prescribing. If they find he has been over-prescribing, this money is deducted from his remuneration.

The other thing that happens is that there are certain items that fall into the no-man's-land of drugs or food. I am thinking of patients who have liver damage. Certain preparations are challenged as a food, and the practitioner is told: "This is not to be given under National Health Service. Therefore, we are deducting the cost from your remuneration." He may appeal, but the appeal may have to go all the way through the National Health Service channels.

Now, will it happen in this country? Your guess is as good as mine, and I believe your feeling of the tenor of the situation in America is greater and better than mine.

U. S. Reaction toward Government Medicine is Cause for Alarm

I want to tell you of one thing that astonished me recently. At a meeting in the United States, I heard speak Mr. Hugh Gaitskell, the leader of the British Labor Party, who would have been the Prime Minister had his party been successful in the last election. He addressed an open meeting of middle class people. During the question and answer period, inevitably the question came up, "What is your opinion of the socialized medicine you have in Great Britain?" And his answer was very fluent and elicited what, to me, was an astonishing reaction from the audience.

He replied, "We don't call it socialized medicine. That's what it is called over here. We call it the British National Health Service and if you want my opinion, I consider it the greatest social reform in the history of the British House." He received spontaneous applause from that audience. It may seem naive, but I was astonished and very surprised. The significance of this I will leave to you.

We have the Forand Bill and we have other areas that you are all aware of, where the Federal Government is making inroads but, as I say, I believe this can be understood better by you and your colleagues.

U. S. Can Benefit from Great Britain's Mistake

In conclusion, where did we go wrong? First, we had no organization to meet the government on the same ruthless footing. They used the technique, and I am sure you are aware there is a probability of that here, which is, "Divide and conquer." They divided the profession. One deal for the specialists and another deal for the practitioner, all the time chopping the profession into groups and sub-groups. Although everybody was protesting, there was no one unanimous voice.

Secondly, and I wonder if it is applicable here, is the lack of public support. We tried to rally the people. Although, individually, they had a tremendous liking and respect for the physician as a person, I think in every country there is something of envy for the profession as a whole. I notice here when I go into a shop to buy something, I get this reaction: "Doctor, this is our standard line. You don't want this. You want the deluxe model." Which is three times as much. This is a very unfortunate attitude for the public to have.

We had special conditions that I think were peculiar to Great Britain. We had just emerged from the war. Many physicians had returned from overseas. They were starting a family and they wanted to get out and practice and they didn't take the threat seriously.

I think if we could go back we would have adopted a policy of trying to effect a compromise favorable to us. One which would enable us to give the patient the type of care that we think he needs and deserves and the type of care that can be made possible under our control.

We were warned. We had a long period of warning. We saw it coming and we didn't react to it.

Government Medicine Means a Road of No Return

Will it change? No. Politically, it is dynamite. A politician concerned with getting back into Parliament or Congress or the Senate is not going

to vote for something that the public is against and that is why I don't think our own system will change.

I would like to finish with this thought: The scheme has a lot of very good points; it has a lot of things which make it unpopular with the physician, with the patient and the politician, each for a different reason. Somebody said on the BBC film which I heard last Saturday, "Everybody points the finger and says, 'What a wonderful scheme it is,' but no country yet has felt wealthy enough to introduce the scheme as we did in one slam-bang." But a lot of countries are introducing it piecemeal, and in the Commonwealth and Canada they have schemes of various sorts. Also in Australia, New Zealand, Germany, Italy and the Scandinavian countries. It is coming, not with one move, but piecemeal, and I think it seems inevitable.

Therefore, we have to meet the challenge and give something to the patient which is good for him and good for us.

I think you have in prepayment medical plans an effective challenge to government sponsored health insurance. Over the last few days, I am also aware that there are difficulties with these, both from the patient's and the physician's viewpoint. I urge you to resolve these difficulties.

Why do I say that prepayment medical insurance is an answer to government intervention in the medical field? Simply this, over the last few years in the United Kingdom, over four million patients who belong to the service have voluntarily taken out private prepayment medical insurance. This means they are paying yet again to recover something which they feel is worth having.

The British National Health Service has succeeded because of the integrity of the British physicians who made it work despite their own feelings. The private insurance is expanding rapidly, because the British physicians also want it to work and we are making every effort to see that it does.

I believe, therefore, that prepaid medical insurance, especially the type offered by Blue Shield, will be one answer to the situation which you have here in America.

The future rests in your hands.

Woman's Auxiliary

YOUR COUNTY AUXILIARIES IN ACTION . . .

Ramsey County

Dr. William Lick spoke on Blue Cross and Blue Shield at the March meeting held in the Minnesota Club. Chairman of the St. Paul Heart Council, educational division of the Heart Association, is Mrs. Herman Wolff. This group promotes the distribution of educational material in the form of lectures, films, and talks by doctors for lay groups. These programs will be available for civic and PTA groups. At the April meeting of the Ramsey County Medical Auxiliary held in the Women's City Club, Mrs. Wallace Gleason presented checks to the winners of the Medical Society's essay contest on free enterprise. Mrs. John Teisberg gave awards to the winners in the radio speech contest on tuberculosis sponsored by the Auxiliary. Mr. and Mrs. Henriot of the Theater St. Paul gave an extremely interesting program. They traced different types of acting from the time of Shakespeare to the present day and presented excerpts from plays by way of illustration.

Mower County

The Mower County Medical Auxiliary sponsored a medical career day, April 4, at the YWCA in Austin. About sixty-five girls from Austin High School and other high schools throughout the county were present.

Mrs. Thomas Seery, president, introduced Mrs. Mansur Taufic who presented panelists as they discussed opportunities in the various medical fields.

Miss Edna Gjermundson, industrial nurse at Geo. A. Hormel & Company, explained her field; John Brenner, St. Olaf Hospital anesthetist, outlined opportunities in anesthesia; Mrs. Darrel Yates, Mower County public health nurse, discussed public health nursing, and Mrs. Taufic, who moderated the panel, stressed the opportunities in the field of nurses' education. A question and answer period followed.

Blue Earth County

The Blue Earth County Medical Auxiliary has as its chief interest the nursing school of the Mankato State College and the Mankato Rehabilitation Center. The Auxiliary has purchased a tape recorder for the use of the Center in speech therapy and is considering a request for volunteer time to assist at the Center. Members have voted $180 tuition scholarship for a student nurse at the nursing school. They continue their support of AMEF drug collections.

McLeod County

The McLeod County Medical Society and Auxiliary entertained members of the McLeod County Bar Association and their wives at a dinner meeting at the Garden Supper Club in Hutchinson recently.

The Art of Medicine

PR

Carl H. Woyke, B.A.
Editor

IMAGE OF A PHYSICIAN IN A PATIENT'S MIND'S EYE

What does a patient see in his mind's eye when he thinks of medicine? The medical profession must have the answer to this question before it can effectively develop a sound public relations program.

Business and industry intent to learn what the public thinks have conducted "image" programs.

AMA Communications Director Leo E. Brown explains simply put, an image program is what the customer sees in his mind's eye when he thinks of medicine. He sees the sum total of his own and his family's experiences. Blended with this experience is that which he has read, heard or seen of other people's medical experiences. He sees medicine or his own physician in terms of the psychological and emotional impact he has experienced. This image may be real or imaginary; nevertheless, it is his—and his thoughts, words and actions are based upon this image.

Therefore, before we can develop an effective public relations program it is important that we see ourselves as others see us . . . that we use this information to guide us in determining what part of the mirror needs our attention so that the true image of medicine may be reflected to all America.

Recently the public opinion technique was used by the AMA to determine what people are thinking of the medical profession.

Mr. Brown enumerates the results of the survey which included 1500 personal interviews conducted among a representative cross section of the United States twenty-one years of age and over.

Doctors stand higher on the scale of public favor than do any of fifteen other occupational groups.

Doctors overshadow all other groups when people were asked to name the one occupation they regard most favorably.

Next the AMA attempted to ascertain the image of the physician in general in contrast to two other professions—dentists and lawyers—who charge on a fee-for-service basis.

In the area of human relations, physicians outranked the other two professions in: treating each person as a human being; understanding; warmth and friendliness.

But they also outranked the dentists in: not caring about people's feelings; being too impressed with their own importance; acting as though they know everything.

Quite another image was reflected from the public screen in the service area. While 45 per cent gave physicians credit for "nearly always glad to help when you have an emergency," 22 per cent felt doctors were too busy to give each person full attention, 15 per cent felt doctors make people wait unnecessarily for service, and the same number felt that doctors were too difficult to see. While in the favorable category physicians outranked dentists and lawyers—they also had more unfavorable comments chalked up against them.

A lack of satisfaction with service, as distinct from medical care, is definitely one of the public images that needs polishing.

In the area of financial relations, there are some obsessed with the reflection of a dollar sign which represents their image of medicine. While 35 per cent of the general public sees the doctor in a favorable light insofar as financial relations are concerned, we find 18 per cent who have mixed feelings, and another 18 per cent who are critical. Despite the fact that the physician still outranks the dentist and the lawyer, he is criticized for: often charging more than expected; making more money than he is worth; not understanding people's money problems—and, being interested mainly in making money.

In general, the problem here is one of communications and the resultant lack of understanding. Because of this misunderstanding, there is a close association be-

tween the idea that doctors are too money-minded and that their charges are higher than expected.

The public image of the doctor is certainly far from all bad. In a relationship that is so close and personal, it was rather amazing to find that 56 per cent of those interviewed reported no unsatisfactory experience with a doctor. Of the 44 per cent who had an unsatisfactory experience, 32 per cent reported that the experience was of such a nature as to prompt them to change doctors.

This analysis revealed three major areas of dissatisfaction—service, communications and finances. The individual physician, therefore, has a very real obligation to the profession to do all within his power to maintain high quality service, to take the time to discuss with the patient his physiological well being, and to impress upon him his sincere interest, plus a frank discussion of the cost involved.

Another phase of our survey was designed to measure the public image of the American Medical Association. Seventy-one per cent of the general public have heard about the AMA. Of this number, 12 per cent know a fair amount about the Association, 22 per cent know a little about the AMA, and 37 per cent have heard about the AMA but know practically nothing about it.

Among those who have heard of the AMA, 63 per cent feel the AMA encouraged the development of new drugs and medicines, in contrast to 3 per cent who feel the Association is slow to encourage the development of new drugs.

Fifty-seven per cent feel the AMA encourages the development of new methods of treatment, while 4 per cent feel it is slow to encourage the development of new methods of treatment.

Fifty-five per cent feel the AMA does everything it can to further health education.

In the field of legislation, 42 per cent feel the AMA supports desirable laws, while 5 per cent feel we do not.

Traditionally, criticisms have been leveled against the AMA for not doing everything it could to encourage an adequate supply of doctors. Now 33 per cent feel we do and 5 per cent feel we try to limit the supply of doctors.

The difference between the positive approach and the negative is considerably reduced when we asked whether the AMA tries to see that everyone, regardless of ability to pay, gets good medical care, 27 per cent saying yes in contrast to 15 per cent saying no.

In the area of medical leadership, the AMA is given credit for having done most to improve the nation's health, although the total vote for government, including state health departments, U. S. Government and city health departments, exceeds slightly that given to the AMA.

The picture is not nearly so encouraging when asked "Who will take the leadership in the future in advancing the nation's health?" The AMA still is out in front, but the opinion that the U. S. Government *will* lead doubles from that expressed on present leadership (9 per cent to 18 per cent). The reasons given here are logical since the U. S. Government has the necessary authority and the financial means to do the job. But in the field of competency, the AMA leads the U. S. Government 57 per cent to 8 per cent.

There is much cause for concern when we view the present and future leadership image of the AMA and the U. S. Government. Strong evidence of people's increased reliance on government is fairly well documented. However, the situation is far from hopeless, for with the present leadership advantage organized medicine now holds there is no reason why this position of leadership cannot be maintained, providing medicine is willing to promote an effective public relations program in the interest of the general public.

Effective medical public relations can no longer be viewed solely as a preventive or holding operation but as a creative, organized activity to strengthen the future of medicine.

The physician is, has been and always will be medicine's severest critic. This is as it should be, providing it is constructive and not destructive.

All too often we lament the fact that there is an organized effort "afoot" to discredit medicine, to soften us up, so that the Federal Government can step in and socialize medicine. This may be true, I do not know, but if it is, the best way to counteract it is not by playing the martyr role. If the chips are down and the lines are drawn, then let us mobilize the full strength of a noble profession for an aggressive, positive attack, concludes Mr. Brown.

Committee Action

COMMITTEE ON MATERNAL HEALTH

Suggested Guide for Obstetric Hospital Practice

An ounce of prevention is especially worth a pound of cure in obstetrics. A ten-year study of maternal deaths in Minnesota has formed the framework for this suggested guide for obstetric practices. All physicians caring for pregnant women must read carefully.

Foreword

A Maternal Mortality Study Committee appointed by the Council of the Minnesota State Medical Association has been engaged for ten years in a continuous study of every reported and otherwise discovered maternal death in the state. The Committee has carefully analyzed the cause of death in each case and has attempted to evaluate objectively the deficiencies of prepartal, intrapartal and postpartal care which might be considered to be contributory factors.

Reports of the Committee's findings and conclusions have been published from time to time in MINNESOTA MEDICINE (see references).

Based on this study and on these reports, the Committee has drawn up a set of carefully considered suggestions for maternal care which have been reviewed and approved by the Maternal Health Committee of the Minnesota State Medical Association, by the Minnesota Chapter of the Academy of General Practice, and by the Minnesota Obstetrical and Gynecological Society.

The Council of the Minnesota State Medical Association, on December 20, 1959, approved the organized set of recommendations which follows as a suggested guide for obstetric hospital practice and has authorized its distribution to physicians and hospitals in the state by the State Board of Health. The Council has authorized its publication in MINNESOTA MEDICINE, so that the principles it embodies may be brought to the attention of all Minnesota physicians.

The Committee offers it as an aid in formulating modern standards for the hospital practice of obstetrics which it believes would appreciably reduce the state's present low maternal mortality rate.

JAMES J. SWENDSON, M.D.,
Chairman,
Committee on Maternal Health

Suggested Guide for Obstetric Hospital Practice

As Recommended by the Committee on Maternal Health and Approved by the Council of the Minnesota State Medical Association

It became increasingly evident after the first five years of the Minnesota Maternal Mortality Study that one way in which the number of maternal deaths still considered preventable could be reduced was by the adoption of relatively uniform standards of obstetric practice by hospitals throughout the state.

The following recommendations are not offered as a complete manual of obstetric practice, but are designed as a concise, available, and practical guide in the areas which the Committee considered to be the source of most of the preventable obstetric mortality and morbidity.

1. Prenatal Care and Records.—

The first prenatal visit should include:

(1) An adequate history and general physical examination.
(2) Pelvic mensuration and evaluation by estimating the transverse diameter of the outlet and the diagonal conjugate of the inlet, and by palpating the pubic arch, the sacrum, and the ischial spines.
(3) Laboratory work-up consisting of a serologic test for syphilis, the determination of hemoglobin or hematocrit, a urinalysis, an Rh determination, and blood typing.
(4) A routine chest x-ray, or a Mantoux test, when practical.

Subsequent prenatal visits should include:

(1) Blood pressure determination.
(2) Urinalysis, at least for albumin.
(3) Weight determination.
(4) Hemoglobin determination, at least once during each trimester.
(5) Abdominal palpation and auscultation of the fetal heart tones during the last two months of gestation.

(6) An adequate follow-up and study of any abnormalities discovered.
(7) Rh antibody titers early in pregnancy and at four to six weeks before the estimated time of delivery on Rh negative patients unless the husband is known to be Rh negative.

2. Hospital Work-up and Records.—

(1) A copy of the essential information from the prenatal record should be made a part of the hospital record and should be available at the time the patient is admitted to the hospital.
(2) Adequate evaluation of the patient's history and physical condition should be made and recorded as soon as practicable after admission.
(3) The hospital record should include pertinent progress notes, a summary of the condition of the patient on discharge, and a final diagnosis.
(4) All orders for treatment should be signed by the physician.

3. Obstetric Consultations.—

(1) Liberal use should be made of consultation. Competent consultants should be selected who have one or more of the following qualifications:
   a. Board certification or the qualifications for certification.
   b. Activity in the practice of obstetrics and full hospital privileges to perform gynecologic surgery.
   c. Recognized ability as an obstetrician in his own community.

(2) Consultation is suggested for.—
   a. Prolonged labor.
   *b. Contemplated forceps delivery above the level of outlet forceps.
   *c. Tranverse, face, compound, or other abnormal presentations.
   *d. Primiparous breech presentation.
   *e. Multiple pregnancy.
   f. Severe toxemia of pregnancy.
   *g. Contemplated termination of pregnancy by cesarean section.
   h. Obstetric hemorrhage before, during, or after parturition.
   i. Other serious complications or complicated diagnostic problems.

4. The Use of Pituitary Extracts.—

Pitocin or synthetic Pitocin (Syntocinon) should be used rather than obstetric pituitrin. When these preparations are used before delivery, it is urged that they be administered intravenously in dilute solution as a slowly-running drip. Experience has shown that this route and this method of administration are preferable to subcutaneous or intramuscular administration.

When intravenous Pitocin solution is administered:

(1) Supervision and attendance by the physician are indicated.
(2) The cervix should be soft and at least partially effaced, and it should be dilatable.
(3) There should be no cephalo-pelvic disproportion.
(4) There should be no malpresentation of the fetus.
(5) The concentration suggested is ten units of Pitocin per liter of a solution of 5 per cent glucose in water.
(6) The rate of administration should not exceed 1.5 cc. of the dilute solution per minute (about 25 drops).
(7) During the first one-half hour of administration, the rate should not exceed .75 cc. per minute.
(8) The administration of intravenous Pitocin solution should be stopped or slowed if contractions last longer than 60 seconds or occur at intervals of less than two minutes; also, if the rate of the fetal heart tones is noted to be less than 110 or more than 160 per minute for longer than three minutes.

Note.—Multiparity adds to hazards of the procedure and should emphasize the need for careful control with increasing multiparity.

5. Obstetric Anesthesia.—

(1) Local anesthesia: Its use is encouraged.
(2) General anesthesia (by inhalation or intravenously):
   a. An appropriate dose of scopolamine or atropine should be given before a general anesthetic is begun.
   b. The same equipment as that noted below under "Spinal Anesthesia" should be available when administering a general anesthetic.
   c. A general anesthetic should be administered only under the supervision of an adequately trained person.
   d. A general anesthetic should be administered very carefully to a patient who has taken food or fluids shortly before or at any time during labor.

(3) Spinal anesthesia:
   a. When a spinal anesthetic is administered:
      i. Intravenous fluids should be running through a No. 18 needle.
      ii. Oxygen should be available for administration under positive pressure.

*Attendance by the consultant during delivery should be considered.

iii. Vasopressors should be available.
iv. Adequate suction equipment should be on hand.

b. For cesarean section, the maximum dose of the anesthetic agent should be approximately 75 mg. for Procaine, 8 mg. for Tetracaine or their equivalents for other similar preparations.

c. About one-half of the maximum dosage used for cesarean section should be administered for vaginal delivery.

Note.—Spinal anesthesia is poorly tolerated by pregnant women and dosages should be substantially less than for general surgical procedures.

6. The Observation of Patients in Labor and Immediately Postpartum.—

(1) No food should be ingested during active labor.
(2) In early labor, evalution of the character of the labor should be made, and frequent checks should be made of the patient's blood pressure, of the fetal heart rate, and of the condition of the cervix.
(3) As labor advances, the intervals between these checks should be shortened.
(4) Postpartum, the blood pressure, the height and firmness of the uterine fundus, and the amount of vaginal bleeding should be checked every fifteen minutes for the first hour and every one-half hour for the second and third hours.
(5) The findings of the above observations should be recorded on the chart.

7. The Management of Severe Hypertensive Toxemia.—

(1) Hospitalization is imperative.
(2) Consultation is advised.
(3) Bed rest is indicated.
(4) The restriction of sodium intake is indicated.
(5) The administration of diuretics is indicated.
(6) Vasodilator drugs (which improve cerebral and renal circulation) should be administered for the lowering of blood pressure. Their use parenterally in adequate doses is indicated.
(7) Magnesium sulfate solution intramuscularly, given in doses of 5 grams every four hours, may be used for its sedative and anticonvulsant effect. The administration of magnesium sulfate should be discontinued if the urinary output becomes less than 100 cc. for four hours and/or the patellar reflexes disappear.
(8) Large doses of barbiturates are best avoided because of their action of depressing cerebral oxygenation.
(9) Severe or fulminating preeclampsia which does not respond to the measures suggested above should be treated by induction of labor, if it is feasible, or by cesarean section, if induction is not feasible.
(10) Cesarean section is not indicated during the active phase of convulsive toxemia.

8. The General Management of Obstetric Hemorrhage.—

(1) Blood loss should be replaced as soon as possible with whole blood.
(2) While blood is being cross-matched, one or more intravenous infusions of glucose solution in water should be administered using number 18 gauge needles.
(3) When indicated, plasma expanders, such as Dextran, also may be administered intravenously.
(4) Consultation is indicated.

9. The Management of Postpartum Hemorrhage.—

(1) Prophylaxis: Postpartum hemorrhage often may be anticipated and the proper preparations made for combating it. Blood typing, cross-matching, and the starting of intravenous fluids may be done in advance when such conditions as multiple pregnancy, operative delivery, prolonged labor, the overdistended uterus of hydramnios and uterine inertia alert the attending physician to anticipate excessive postpartum bleeding.
(2) Active management: If preparations have not been made for the patient who bleeds postpartum, the following measures are indicated:
   a. Blood should be drawn for cross-matching and fluids should be started intravenously through a number 18 gauge needle.
   b. Intravenous oxytocics should be given which include the continuous administration of a dilute Pitocin solution.
   c. The placenta should be examined.
   d. The vagina, the cervical canal and the uterine cavity should be explored, but without deep anesthesia.
   e. Any lacerations discovered during examination should be sutured.
   f. Blood loss should be replaced with whole blood.

10. The General Management of Late Pregnancy Bleeding (Antenatal Hemorrhage).—

(1) If there is significant blood loss, intravenous fluids should be started and given through a No. 18 gauge needle while an adequate amount of blood is being cross-matched for blood replacement.
(2) Rectal examination is contraindicated.

(3) Frequent abdominal examinations are indicated and should include:
   a. Palpation for a possible increase in the height of the fundus of the uterus and for increasing tone and tenderness of the uterus.
   b. Auscultation of the fetal heart tones for changes in rate.

(4) When the duration of the gestation is less than 34 or 35 weeks, expectant treatment may be followed for a time if severe premature separation of the placenta can be ruled out by such signs as painless bleeding, a soft, relaxed uterus, a normal fetal heart rate and no increase in the height of the fundus of the uterus. With these findings, the presumptive diagnosis is placenta previa.

(5) If, with the above findings, bleeding subsides, and expectant treatment is decided upon in the hope of increasing the chances of fetal survival, it is advisable to keep the patient in the hospital and to have 1,000 cc. of whole blood available for transfusion at all times.

(6) If, with the same findings, bleeding continues or recurs, vaginal examination (as described below) is indicated even though the presumptive diagnosis is placenta previa and the duration of the gestation is less than thirty-four or thirty-five weeks.

(7) If the duration of gestation is thirty-five weeks or more, or if the estimated weight of the fetus is five pounds or more, and bleeding continues or recurs, a diagnostic vaginal examination is indicated.

(8) Vaginal examination, when indicated, should be done under a double set-up, that is, preparations should be made for immediate cesarean section if it becomes necessary.

(9) An adequate amount of cross-matched blood should be available and a number 18 gauge needle should be in a vein with fluids running before doing a diagnostic vaginal examination.

11. The Management of Placenta Previa.—

(1) If complete or central placenta previa is demonstrated by careful vaginal digital examination, the termination of pregnancy by cesarean section is indicated.

(2) The management of lesser degrees of placenta previa requires judgment. Some cases may require termination of the pregnancy by cesarean section and others may require only simple rupture of the fetal membranes. Choice of the method of treatment should be made by evaluating such factors as parity, the condition of the cervix, the status of the fetus, and the degree of placenta previa demonstrated.

12. The Management of Premature Separation of the Placenta.—

If the history and an examination (including, if necessary, a sterile vaginal examination) lead to a diagnosis of premature separation of the placenta, the following appropriate measures are advised:

(1) Blood should be made available for the replacement of significant blood loss.

(2) Consultation is indicated.

(3) Five to ten grams of fibrinogen should be made available.

(4) *Clot observation tests* should be done hourly, as follows: Five cc. of blood are drawn and placed in a small test tube. At adequate fibrinogen levels, a firm clot forms which does not lyse during a period of thirty minutes. With a critical lowering of plasma fibrinogen, no clot forms. Between these levels, the formation of a soft clot which lyses in less than thirty minutes indicates a serious fibrinogen depletion.

(5) If clot observation tests reveal significant fibrinogen depletion, two grams of fibrinogen should be administered and the dose repeated as shown necessary by hourly tests. This should be done even though the patient is not bleeding.

(6) If the fetus is living and viable, and delivery, as judged by the state of the cervix and the character of the labor, is not imminent, blood loss should be replaced and a cesarean section should be performed.

(7) If the fetus is living and viable, and delivery is imminent, simple membrane rupture should be done and shock should be controlled by blood replacement.

(8) It may be advisable to stimulate labor by instituting an intravenous Pitocin drip after membrane rupture has been accomplished.

(9) If intravenous Pitocin drip is used to stimulate labor, it should be continued postpartum until the danger of hemorrhage has passed.

(10) If the fetus is dead, conservative management is usually indicated:
   a. Rupture of the membranes should be carried out as soon as it is practicable.
   b. The replacement of blood loss should be made.
   c. The institution of an intravenous Pitocin drip may be required to stimulate labor.

(11) If the fetus is dead, radical management with delivery by cesarean section is indicated only on rare occasions in the presence of severe abruptio placentae when the probability of vaginal delivery being accomplished within a reasonable length of time is unlikely.

(12) Every attempt should be made to correct shock before resorting to delivery by cesarean section.

(Continued on Opposite Page)

In Memoriam

HUGH BEALS

Dr. Hugh Beals, a St. Paul physician, died May 2, 1960, at the age of seventy-six, at his winter home in La Jolla, California.

A native of Cumberland County, Illinois, he was graduated from Hahnemann Medical College and Hospital in Chicago and began practicing in St. Paul in 1909. He retired in 1949. He was a member of the Ramsey County Medical Society, the Minnesota State Medical Association and the American Medical Association.

He is survived by his wife, Kate; a daughter, Mrs. Sarah Holzenbach, and four grandchildren.

CLIFTON A. BOREEN

Dr. Clifton A. Boreen, Minneapolis dermatologist, died May 1, 1960, at the age of sixty.

A life member of the Hennepin County Medical Society and the Minnesota State Medical Association, Doctor Boreen was born in Stillwater, Minnesota. He was a graduate of the University of Minnesota Medical School and was a charter member of the Sigma Nu Fraternity.

Doctor Boreen retired in 1952 after fifty years of practice in Minneapolis. He was a medical officer in World War I; a member of the Mayflower Congregational and AF & AM.

Survivors are his wife, Leilla; and a sister, Mrs. Burke Thompson, Minneapolis.

Committee Action

13. Note on Accouchement Forcé.—
Manual dilation of the cervix for forcible delivery of the fetus is an outmoded procedure fraught with proven dangers, and it should never be done.

14. Note on Internal Version and Extraction.—
This procedure has been shown to be extremely hazardous for both mother and infant, and it has very limited indications and applications.

THOMAS P. MARTIN

Dr. Thomas P. Martin, Arlington physician, died May 4, 1960, at the age of eighty-six.

Doctor Martin was born in Piper City, North Dakota. At the age of nine he moved to Page, North Dakota, where he received his preliminary education. He graduated from the University of Michigan in 1902.

He served as a captain in the Medical Corps before coming to Arlington in 1930. He was a member and served on the Board of the Arlington Methodist Church and also belonged to the American Legion and the Masons. Doctor Martin was a member of the Scott-Carver Medical Society and was a fifty-year member of the Minnesota State Medical Association and the American Medical Association.

Survivors include his wife, Hope A., Minneapolis; a son, Dr. Dwight L. Martin, South St. Paul; and three daughters, Mrs. Chester Webb, Cavalier, North Dakota, Mrs. W. P. Laughlin, Elmhurst, Illinois, and Mrs. Lee Christenson, Rochester, Minnesota.

JOSEPH J. McCARTHY

Dr. Joseph J. McCarthy, St. Paul police surgeon for twenty-six years, died April 22, 1960. He was sixty-seven years of age at the time of his death.

He was born in Clinton, Iowa, and attended the University of Iowa. He was graduated from the University of St. Louis Medical School and served his internship at St. Mary's Hospital in Minneapolis.

In 1929 he entered general practice in St. Paul. He was appointed a police surgeon July 1, 1934, and had served in that position since in addition to his private practice.

Doctor McCarthy was a member of the Ramsey County Medical Society, the Minnesota State Medical Association and the American Medical Association.

Surviving are his wife, Florence; a daughter, Joanne McCarthy, Virginia, Minnesota; three sons, Jean J., John P., and Joseph D., all of St. Paul; and two sisters, Mrs. John F. Devlin, Clinton, Iowa, and Alice McCarthy, Riverside, California.

ALFRED E. WALKER

Dr. Alfred E. Walker, a former Duluth physician and surgeon, died April 14, 1960, at St. Joseph's Hospital in St. Paul, at the age of ninety-seven.

Doctor Walker, who practiced medicine in Duluth for sixty-one years, moved to St. Paul in 1951 following his retirement.

The deceased was born in Ontario, Canada, and was a graduate of Western University, London, Ontario, and Bellevue Hospital Medical College, New York.

Doctor Walker was a member of St. Louis County Medical Society and was granted Life Membership in the Minnesota State Medical Association in 1952. He was also a member of the American Medical Association.

Surviving are two sons, Dr. Arthur E. Walker, St. Paul, and Shores A. Walker, Detroit, Michigan. There are four grandchildren and seven great-grandchildren.

Minnesota Blue Shield

The Minnesota medical profession is continuing to lend outstanding support to the program of its Blue Shield organization. In recent months, professional societies and individual participating doctors have demonstrated their loyalty and interest in a truly gratifying manner.

Since January, Blue Shield officials have made a series of appearances before professional groups, including both county societies and those representing specialized fields.

Approximately 30 of these groups have adopted resolutions endorsing the Blue Shield program, with a large number specifically expressing approval of the addition of diagnostic x-ray and laboratory benefits to Blue Shield contracts.

In addition, participating doctors have co-operated in helping to disseminate Blue Shield information to their patients. Many doctors have been enclosing messages concerning Blue Shield in their monthly statements to patients. Blue Shield is providing additional quantities of these messages and it is hoped that doctors will continue to make use of them. This type of personal recommendation by physicians is perhaps the most effective means of maintaining and increasing Blue Shield's enrollment.

The Senior Citizen Plan has also received excellent support from physicians. The literature and application forms which were sent to all participating doctors, along with a placard for displaying the material were well received. Literature and applications for standard Blue Shield contracts are also being sent to participating doctors. It is hoped that the Blue Shield placard will be retained to display Blue Shield literature and applications and that it will be given a permanent place in doctors' offices.

Doctors are also receiving a dignified Blue Shield poster intended for use in waiting rooms. Use of the poster will stimulate interest in Blue Shield and create opportunities for doctors and their office personnel to explain the superior coverage offered by Blue Shield.

Conveying Blue Shield information to subscribers and the public at large remains one of the major challenges of the current program. Confusion and uncertainty about the Blue Shield plan continue to exist.

An intensive program of education and promotion is being carried on to counteract this situation. The foundation of the program is a consistent schedule of statewide radio advertising, in which Blue Shield is sponsoring numerous news programs throughout the day.

Blue Shield has also expanded its use of highway signs throughout the State. A total of 116 Scotchlight signs (8 ft. by 12 ft.) are calling attention to Blue Shield in locations along well-traveled highways.

However, the most effective "advertising message" for Blue Shield is the personal recommendation of participating physicians. It is hoped that the 3,100 doctors of medicine who participate in the Minnesota Blue Shield program will discuss the advantages of this doctor-sponsored plan with their patients at every opportunity.

Members of the doctor's office staff—nurses, receptionists, bookkeepers, business managers—are also in a position to make a valuable contribution to the Blue Shield program. It is hoped that participating doctors will encourage staff members to give patients the facts when patients inquire about Blue Shield.

Pharmacists Support Blue Shield

During its annual convention held in Minneapolis in May, the Minnesota State Pharmaceutical Association adopted a resolution urging members to support the Blue Shield Senior Citizen program.

The Association, representing more than 1,000 Minnesota pharmacists, earlier in May sent Blue Shield literature and application forms to pharmacists requesting that they display this material on the prescription counters of their drug stores.

Henry Moen, executive secretary of the Association, said: "The pressure for government controlled medicine is a threat to all of the health professions, pharmacy included. We pharmacists believe it is our duty to support Blue Shield in its program providing low-cost medical coverage on a voluntary basis."

Minnesota State Medical Association Roster-1960

Officers

Clarence Jacobson, M.D.	*President*	Chisholm
C. L. Oppegaard, M.D.	*President-Elect*	Crookston
W. E. Macklin, M.D.	*First Vice President*	Willmar
L. M. Hammar, M.D.	*First Vice President (to take office January 1, 1961)*	Mankato
G. J. Strewler, M.D.	*Second Vice President*	Duluth
E. W. Johnson, Jr., M.D.	*Second Vice President (to take office January 1, 1961)*	Rochester
B. J. McGroarty, M.D.	*Secretary*	Saint Paul
K. W. Anderson, M.D.	*Treasurer*	Minneapolis
H. M. Carryer, M.D.	*Speaker, House of Delegates*	Rochester
J. L. Falls, M.D.	*Vice Speaker, House of Delegates*	Red Wing
Harold W. Brunn	*Executive Secretary*	Saint Paul

Councilors

(Terms expire December 31 of year indicated)

First District
J. M. Stickney, M.D. (1962) ..... Rochester

Second District
W. B. Wells, M.D. (1962) ..... Jackson

Third District
P. E. Hermanson, M.D. (1961) ..... Hendricks

Fourth District
C. G. Sheppard, M.D. (1960) ..... Hutchinson
A. M. Jensen, M.D. ..... Brownton
Councilor-elect (to take office Jan. 1, 1961)

Fifth District
J. P. Medelman, M.D. (1961) ..... St. Paul

Sixth District
Donald McCarthy, M.D. (1963)
(Chairman) ..... Minneapolis

Seventh District
W. W. Will, M.D. (1961) ..... Bertha

Eighth District
C. L. Oppegaard, M.D. ..... Crookston
Geo. A. Sather, M.D. ..... Fosston
Councilor-elect (to take office Jan. 1, 1961)

Ninth District
R. P. Buckley, M.D. (1962) ..... Duluth

House of Delegates, American Medical Association

Members

R. L. J. Kennedy, M.D. (1960) ..... Rochester
J. M. Stickney, M.D. ..... Rochester
Delegate-elect (to take office Jan. 1, 1961)
A. O. Swenson, M.D. (1960) ..... Duluth
A. E. Ritt, M.D. (1961) ..... St. Paul
O. J. Campbell, M.D. (1961) ..... Minneapolis

Alternates

R. H. Wilson, M.D. (1960) ..... Winona
Clarence Jacobson, M.D. (1960) ..... Chisholm
E. M. Hammes, M.D. (1961) ..... St. Paul
C. L. Oppegaard, M.D. (1961) ..... Crookston

Scientific Committees

AGING

Leo A. Nash, M.D., *Chairman* ..... St. Paul
C. A. Anderson, M.D. ..... Hector
Jeannette L. Baker, M.D. ..... Fergus Falls
Ronald W. Barr, M.D. ..... Montevideo
J. Gordon Beaton, M.D. ..... Northfield
R. H. Conley, M.D. ..... Mankato
Albert J. Greenberg, M.D. ..... Minneapolis
Kenneth R. Larson, M.D. ..... St. Paul
Walter S. Neff, M.D. ..... Virginia
Valentine O'Malley, M.D. ..... St. Paul
H. B. Sweetser, M.D. ..... Minneapolis
Clark W. Truesdale, M.D. ..... Glencoe
Vernon A. Vix, M.D. ..... Worthington
W. E. Wellman, M.D. ..... Rochester

ANESTHESIOLOGY

T. H. Seldon, M.D., *Chairman* ..... Rochester
Margaret C. Anderson, M.D. ..... St. Paul
J. W. Baird, M.D. ..... Minneapolis
J. H. Crowley, M.D. ..... St. Paul
Richard C. Gaard, M.D. ..... Minneapolis
F. C. Jacobson, M.D. ..... Duluth
Robert C. Knutson, M.D. ..... St. Paul

BLOOD AND BLOOD BANKS

T. H. Seldon, M.D., *Chairman* ..... Rochester
Paul F. Dwan, M.D. ..... Minneapolis
J. W. Edwards, M.D. ..... St. Paul
Wendell H. Hall, M.D. ..... Minneapolis
William V. Knoll, M.D. ..... Brainerd
R. W. Koucky, M.D. ..... Minneapolis
Donald J. Nollet, M.D. ..... Hibbing
N. C. Plimpton, Jr., M.D. ..... Minneapolis
William E. Proffitt, M.D. ..... Minneapolis
Howard M. Wikoff, M.D. ..... Crookston

CANCER

(Three-year appointment)

D. E. Stewart, M.D. (1960) *Chairman* ..... Crookston
David P. Anderson, Jr., M.D. (1961) ..... Austin
Don S. Childs, M.D. (1962) ..... Rochester
Philip F. Eckman, M.D. (1961) ..... Duluth
W. O. Finkelnburg, M.D. (1962) ..... Winona
G. F. Hartnagel, M.D. (1962) ..... Red Wing
Paul Heise, M.D. (1961) ..... Winona
C. R. Hitchcock, M.D. (1962) ..... Minneapolis
N. K. Jensen, M.D. (1960) ..... Minneapolis
Arnold J. Kremen, M.D. (1962) ..... Minneapolis
Leonard A. Lang, M.D. (1961) ..... Minneapolis
John J. Muller, M.D. (1960) ..... Hibbing
F. M. Owens, Jr., M.D. (1961) ..... St. Paul
Lyle Tongen, M.D. (1962) ..... St. Paul

CHILD HEALTH AND IMMUNIZATION

R. O. Bergan, M.D., *Chairman* ..... Duluth
